

Stream-Driven Galaxy Formation at High Redshift

Avishai Dekel
The Hebrew University of Jerusalem

KooFest, Santa Cruz, August 2011

Outline

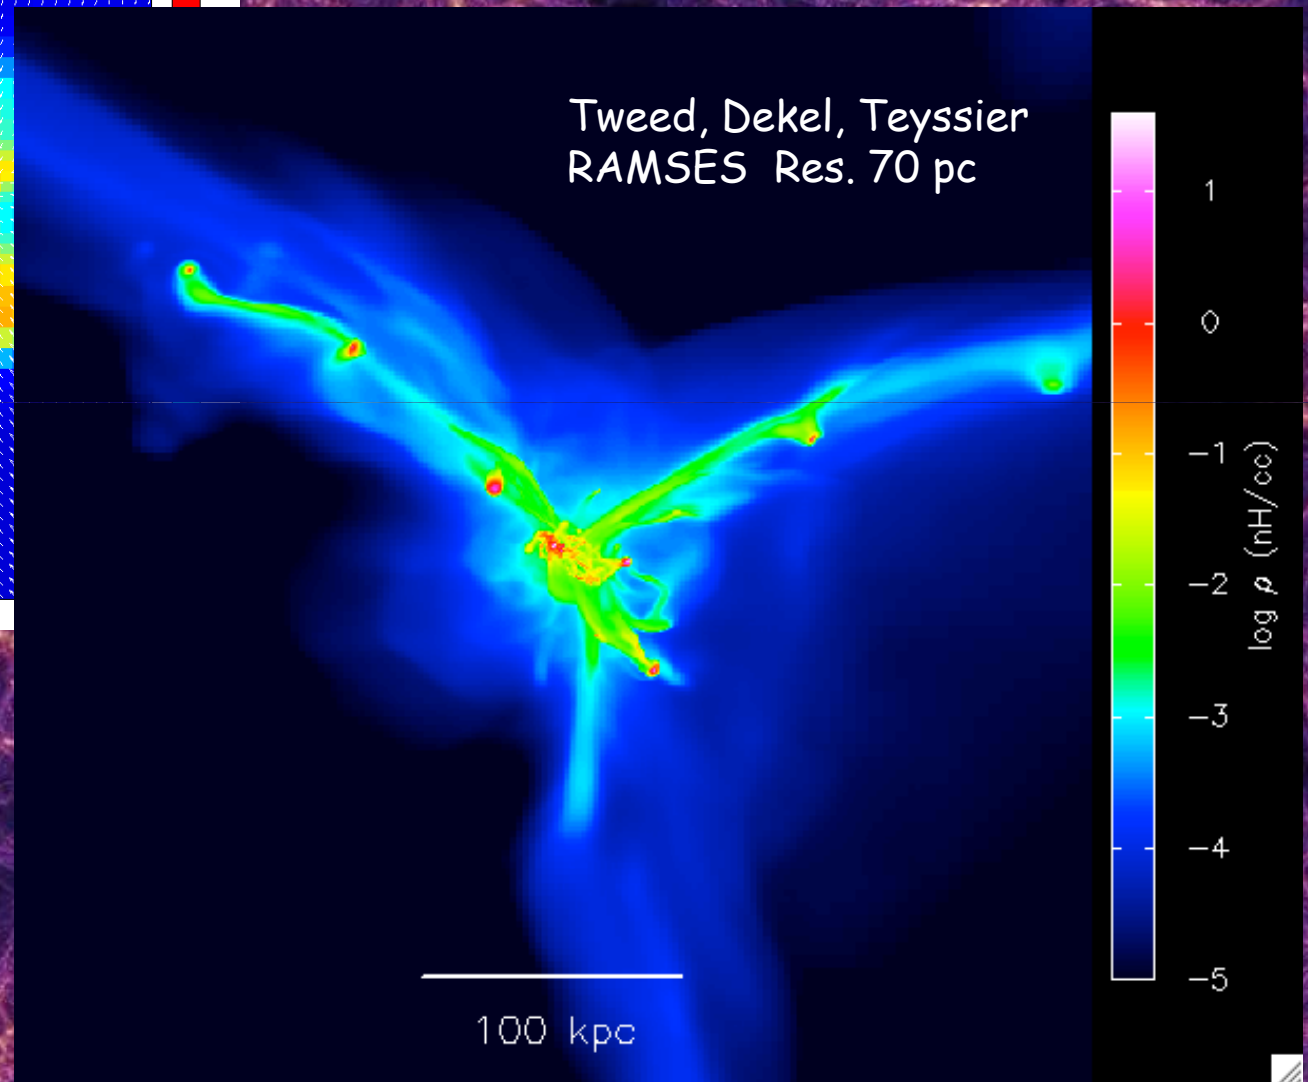

1. Streams in pancakes from the cosmic web (Hahn)
2. **Is angular momentum conserved in disk formation?**
3. Outflows and inflows
4. Observing cold streams (Fumagalli, Kasen)
5. SFR and quenching in stream-fed disks (Krumholz)
6. Violent disk instability, clumpy disks (Ceverino, Mozena, Burkert, Genzel, Newman)
7. Evolution of instability (Cacciato, Forbes)
8. **Instability-driven bulge and black hole**

1. Streams in Pancakes from the Cosmic Web

Danovich, Dekel, Hahn, Teyssier 2011; Pichon et al. 2011
AMR cosmological simulation MareNostrum
RAMSES, resolution 1 kpc, 350 galaxies, at $z=2.5$

Hahn, Dekel, Ceverino, Primack et al. 2011; Kimm et al. 2011
AMR cosmological zoom-in simulations
ART, resolution 35-70 pc, 7 galaxies, at $z=7-1$

Streams riding DM filaments of Cosmic Web

2. Is Angular Momentum Conserved in Disk Formation?

Danovich, Dekel, Hahn, Teyssier 2011
Hahn, Dekel, Ceverino, Primack et al. 2011

Pichon et al. 2011; Kimm et al. 2011

In-streaming \rightarrow Extended Rotating Disk

- AM by transverse motion of streams - impact parameter
- Streams transport AM into the inner halo
- One stream is dominant
- Higher J/M at later times \rightarrow inside-out disk buildup

Angular Momentum on Halo Scale

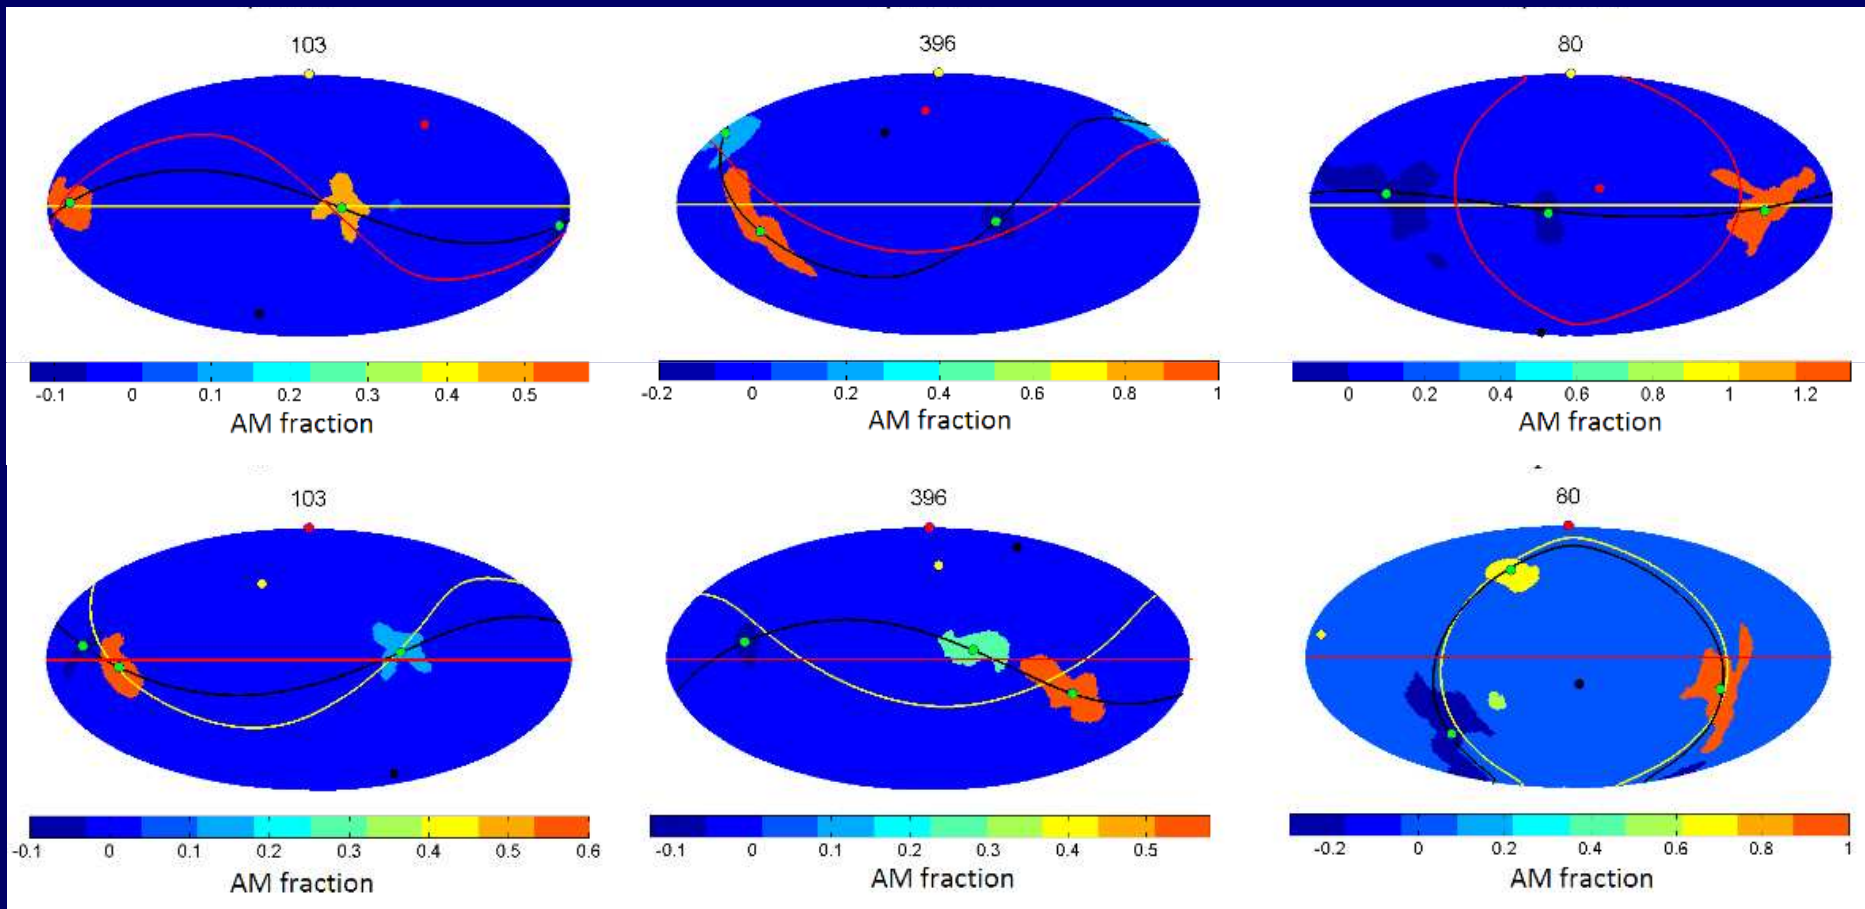

Only little correlation between stream plane and AM at R_v

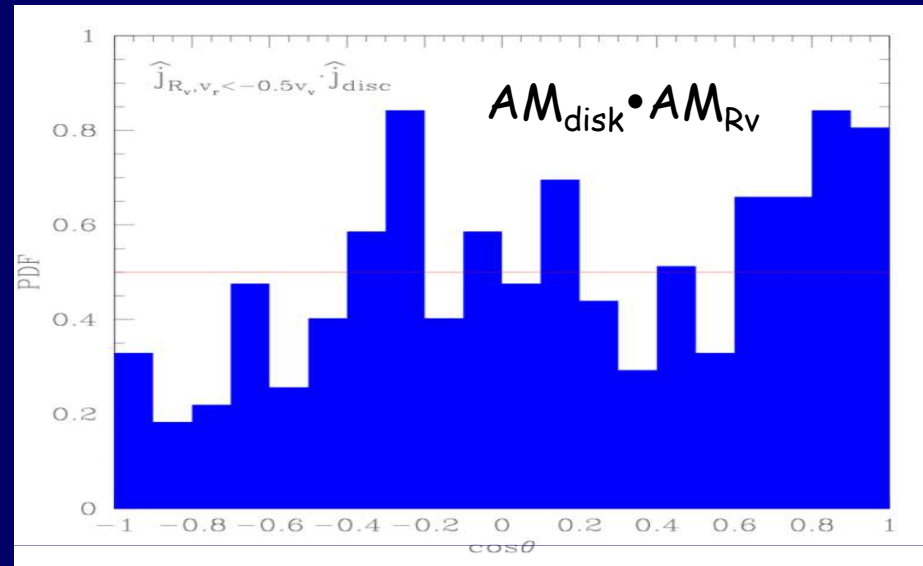

Most of the AM in one stream

Most of the AM in one Stream

Disk is not aligned with AM at $r > 0.3R_{\text{vir}}$

AM Exchange in the Inner Halo

Ceverino, Dekel, Bournaud, Primack
ART 70-pc resolution

Is AM amplitude conserved
to within a factor of 2?

MW1

SFG1

MW3

disk in
pancake
frame

Planes: Disk versus Pancake

A weak correlation:
Disk spin tends to lie in the pancake

Tidal Torque Theory: the spin tends to align with the intermediate eigenvector of the tidal tensor

3. Outflows and Inflows

Theory Challenge: Inflow and Outflow

- What drives the massive outflows in massive galaxies?
 - How do the outflows affect the inflows?
- Need to maintain $\text{Inflow} + \text{Reservoir} = \text{SFR} + \text{Outflow}$

Outflows and Inflows

Inflow-disk-outflow

Tweed, Dekel, Teyssier

RAMSES 70-pc resolution

Outflows find their way out through the dilute medium
no noticeable effect on the dense cold rapid inflows

4. Observing Cold Streams

Emission: *Goerd*t et al. 2010, *Kasen* et al. 2011

Absorption: *Fumagalli* et al. 2011, *Goerd*t et al. 2011

ART code (Klypin, Kravtsov)

Simulations: *Ceverino*, *Dekel*, *Bournaud* 2010

Lyman-alpha from Cold streams

Fardal et al 01; Furlanetto et al 05; Dijkstra & Loeb 09
Goerdt, Dekel, Sternberg, Ceverino, Teyssier, Primack 09

$T=(1-5)\times 10^4$ K $n=0.01-0.1$ cm⁻³ $N_{\text{HI}}\sim 10^{20}$ cm⁻² pressure equilib.

$L \sim 10^{43-44}$ erg s⁻¹

Surface brightness

Cold streams as Lyman-alpha Blobs

Goerdt,
Dekel,
Sternberg,
Ceverino,
Teyssier,
Primack 09

Matsuda et al 06-09

Lyman-alpha Luminosity Function

Isophotal area and kinematics also consistent with data

Lya Image - radiative transfer

Kasen et al 11: including Lya multiple scattering,
UV bkgd, Fluorescence from stars

Lyman-alpha Emission (LAB)

Kasen

Radiative transport of UV & Ly α , fluorescence from stars, dust
Kasen, Ceverino, Fumagalli, Dekel, Prochaska, Primack

Inflowing (clumpy) streams provide an extended source of cold hydrogen

Energy is provided (in comparable fractions) by:

1. inflow down the gravitational potential gradient
2. fluorescence by stars

Yet to be incorporated: AGN, enhanced outflows

Gravity Powers Lyman-alpha Emission

$$E_{heat}(r) = f_c \dot{M}_c \left| \frac{\partial \phi}{\partial r} \right|$$

$$E_{heat} \approx 1.2 \times 10^{43} \text{ erg s}^{-1} f_c M_{12}^{1.82} (1+z)_4^{3.25}$$

Half the luminosity
outside $0.3R_v$

LABs from galaxies at $z=2-4$ are inevitable
Have cold streams been detected ?

Gravitational heating is generic (e.g. clusters)

background source

Lya Absorption

HI column density
central source

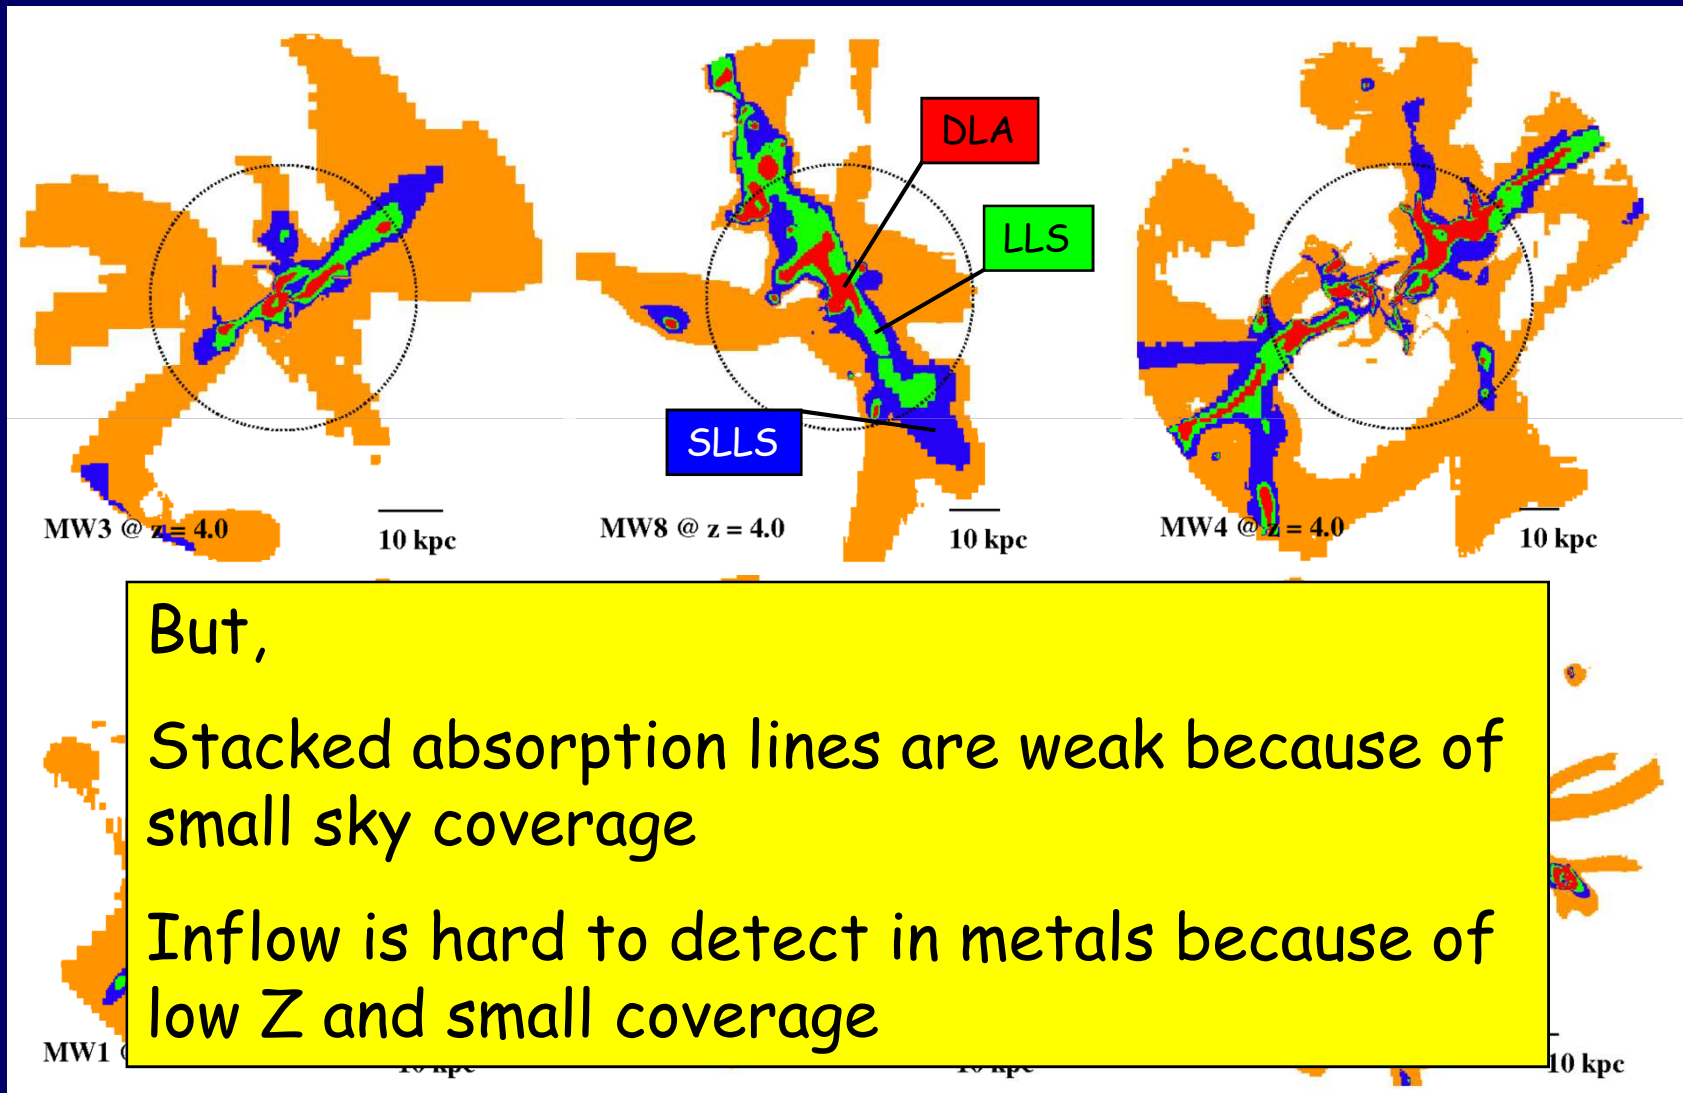

Absorption line profile is weak because of low sky coverage
Inflow signal consistent with observations (Steidel et al. 10)
Inflow undetectable in metals because of low Z and coverage

Cold Streams as LLS and DLAS

Fumagalli

Fumagalli, Prochaska, Kasen, Dekel, Ceverino, Primack 11

But,

Stacked absorption lines are weak because of small sky coverage

Inflow is hard to detect in metals because of low Z and small coverage

HI Absorption Systems

Fumagalli, Prochaska, Kasen,
Dekel, Ceverino, Primack 11

Stacked absorption line profile is weak because of low sky coverage

Inflow signal consistent with observations (Steidel et al. 10)

Inflow undetectable in metals because of low Z and coverage

5. High SFR at $z \sim 2$,
Low SFR and High Gas Fraction at $z > 2$

Dekel et al. 2009
Krumholz, Dekel 2011

Cosmological inflow rate allows high SFR

Dekel et al 09, Nature

$$n(\dot{M}) = \int_0^{\infty} P(\dot{M} | M) n(M) dM$$

From cosmological hydro simulations (MareNostrum)

SFR \sim (1/2) inflow rate

SFR \sim \dot{M} [$M_{\odot} \text{ yr}^{-1}$]

SFR Driven by Accretion?

Mass conservation

$$\dot{M}_{\text{gas}} = \dot{M}_{\text{acc}} - (1 + f_{\text{out}}) \dot{M}_{*}$$

Kennicutt SFR

$$\dot{M}_{*} = \varepsilon \frac{M_{\text{gas}}}{t_{\text{ff}}}$$

Steady state

$$\dot{M}_{\text{gas}} \rightarrow 0 \quad \dot{M}_{*} \rightarrow \dot{M}_{\text{acc}}$$

$$\langle \dot{M}_{\text{baryon}} \rangle = 80 M_{\odot} \text{yr}^{-1} M_{12}^{1.14} (1+z)_3^{2.5}$$

Neistein, Dekel 08

Bouchet et al. 10

But at $z \gg 2$, the SFR cannot catch up with the accretion

$$1. \quad t_{\text{acc}} \sim 2 \text{ Gyr} \quad \frac{t_{\text{sfr}}}{t_{\text{acc}}} \approx \left(\frac{1+z}{3} \right)^{1-1.8} \approx 2.5 \text{ Gyr} (1+z)_3^{-0.7}$$

t_{sfr} by Krumholz, McKee, Tumlinson 09

2. SFR is suppressed by the low metallicity at high z in small galaxies

Krumholz, Dekel 11

SFR Driven by Accretion?

Mass conservation

$$\dot{M}_{\text{gas}} = \dot{M}_{\text{acc}} - \varepsilon \frac{M_{\text{gas}}}{t_{\text{ff}}}$$

SFR

Steady state

$$\dot{M}_{\text{gas}} \rightarrow 0 \quad \dot{M}_* \rightarrow \dot{M}_{\text{acc}}$$

$$\langle \dot{M}_{\text{baryon}} \rangle = 80 M_{\odot} \text{yr}^{-1} M_{12}^{1.14} (1+z)_3^{2.5}$$

Neistein, Dekel 08

Bouchet et al. 10

But at $z \gg 2$, the SFR cannot catch up with the accretion:

$$1. \quad \frac{t_{\text{sfr}}}{t_{\text{acc}}} \approx \left(\frac{1+z}{3} \right)^{1-1.8}$$

t_{sf} by Krumholz, McKee, Tumlinson 09

2. SFR is suppressed by low **metallicity** at high z in small galaxies

Krumholz, Dekel 11

Z-dependent Quenching in small M at high z

Krumholz & Dekel 11

- H_2 is a proxy for SF conditions: cooling (CII, CO) and high density

$$\text{SFR} \sim f_{H_2}$$

Krumholz & McKee 11

- SFR (& H_2): needs shielding by dust and high density against stellar UV

$$f_{H_2} \sim Z \Sigma$$

McKee & Krumholz 09

Low Z - gas heating, H_2 dissociation

High Z - star formation (CII, CO) and H_2

- Metals are ejected by SN, and retained in massive halos

$$f_{\text{eject}} \sim \exp(-M_{11}/3)$$

Dekel & Silk 86

McLow & Ferrara 99

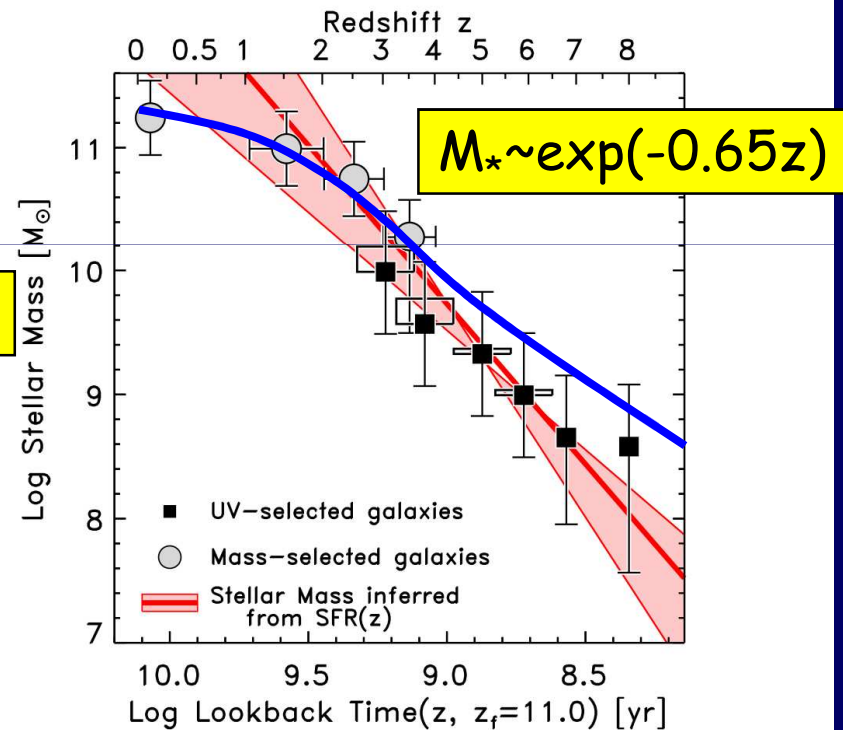

→ SFR is suppressed in $M_V < 10^{11} M_\odot$ at high z

Growing Galaxy: SFR is Growing

Krumholz, dekel 11

Same comoving $n=2 \times 10^{-4} \text{Mpc}^{-3}$ at all z

Papovich et al. 10

Cosmological SFR Density

Integrated over all halos

Krumholz, dekel 11

sSFR for galaxies of fixed mass: Plateau at $z=2-8$

Non-ejective feedback \rightarrow delayed SFR
gas accumulates at $z > 4$, forms stars at $z = 1-3$

SFR > Accretion Rate at z=1-2

Non-ejective feedback \rightarrow delayed SFR
gas accumulates at $z > 4$, forms stars at $z = 1-3$

Very High Gas Fraction at High z

Krumholz, dekel 11

6. Violent Disk Instability: Clumpy Disks at High Redshift

Isolated galaxy simulations:

Noguchi 99; Immeli et al. 04ab; Bournaud, Elmegreen, Elmegreen 06, 08
now reaching 1-pc resolution for 1-Gyr

Zoom-in cosmological simulations:

Dekel, Sari, Ceverino 09; Agertz et al. 09; Ceverino, Dekel, Bournaud 10;
Genel et al 11

ART, RAMSES, GADGET with 50-pc resolution to $z=1$

Violent Disk Instability

High gas density \rightarrow disk unstable

Giant clumps and transient features:
processes on dynamical timescales

$$Q \propto \frac{\sigma \Omega}{G \Sigma} \leq 1$$

$$R_{\text{clump}} \propto \frac{G \Sigma}{\Omega^2}$$

Noguchi 99

Immeli et al. 04

Bournaud, Elmegreen,
Elmegreen 06, 08

In cosmology:

Dekel, Sari, Ceverino 09

Agertz et al. 09

Ceverino, Dekel,
Bournaud 10

Self-regulated at $Q \sim 1$ by torques and encounters \rightarrow high $\sigma/V \sim 1/4$

Torques induce inflow, e.g. rapid clump migration \rightarrow bulge formation

Cosmological steady state: migration and replenishment, bulge \sim disk

Star formation and feedback in clumps (to be understood)

Dekel, Sari,
Ceverino 09;

Ceverino, Dekel,
Bournaud 10

From $z>3$ to $z=1.4$

Clumpy Disk in a cosmological steady state

Gravitational instability is robust at $z > 1$, because of high density and high gas fraction due to intense accretion (Cacciato)

Dekel, Sari, Ceverino 09;
Ceverino, Dekel, Bournaud 10
Primack

Dependence on M and z

f_{gas} is higher for small M and high z (e.g. Z -dependent SFR)
downsizing of star formation

If galaxies are unstable disks with $Q \sim 1$,
galaxies of lower M and higher z :

- are more dispersion dominated

$$\frac{\sigma}{V} \approx 0.4 f_{\text{gas}}$$

- have relatively more massive clumps

$$\frac{M_{\text{clump}}}{M_{\text{baryon}}} \approx 0.2 f_{\text{gas}}^3$$

- migrate faster to a bulge and BH

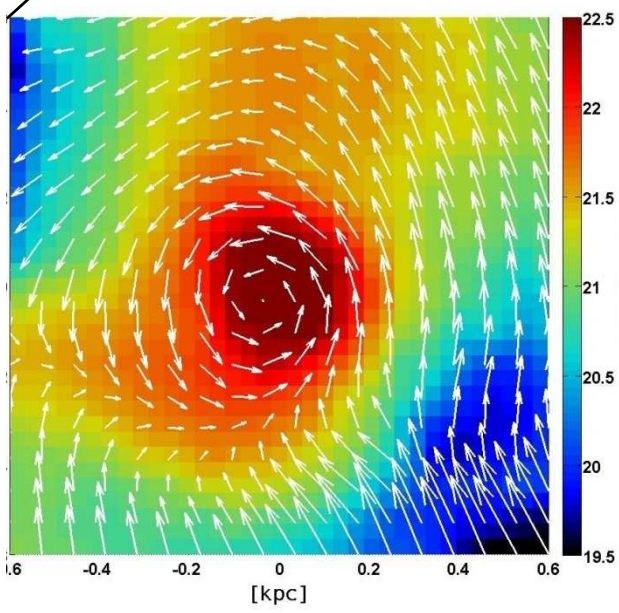

$$\frac{\dot{M}}{M_{\text{baryon}} / t_{\text{dis}}} \approx 0.2 f_{\text{gas}}^3$$

- maintain the instability longer (instability downsizing)

Clump Support: The Clumps are Spinning

Ceverino

Clump Kinematics Under Beam Smearing

$$M_c = 2 \times 10^9 M_\odot, R_c = 0.4 \text{ kpc}, V_{\text{circ}} = 125 \text{ km s}^{-1}, V_{\text{rot}} = 114 \text{ km s}^{-1}$$

8. Violent Disk Instability: Growing a Bulge and a Black Hole

Bournaud, Dekel et al. 2011

Violent Disk Instability \leftrightarrow Inflow to Center

Self-regulated Toomre instability at $Q \sim \sigma\Omega/\Sigma \sim 1$

$$\frac{M_{\text{disk}}}{M_{\text{tot}}} \approx \sqrt{2} \frac{\sigma}{V}$$

$$\frac{M_{\text{clump}}}{M_{\text{disk}}} \approx \frac{1}{2} \left(\frac{\sigma}{V} \right)^2$$

$$\dot{M}_{\text{inflow}} \approx 0.2 \frac{M_{\text{disk}}}{t_{\text{dyn}}} \left(\frac{\sigma}{V} \right)^2$$

1. Torques between perturbations drive AM out and mass in (e.g. clump migration)

Gammie 01; Dekel, Sari, Ceverino 09

2. Inflow down the potential gradient provides the energy for driving σ to $Q \sim 1$ and it compensates for dissipative losses

Krumholz, Burkert 10; Cacciato, Dekel 11

$$\dot{M}_{\text{inflow}} \approx 25 M_{\odot} \text{yr}^{-1} M_{\text{disk},11} (1+z)_3^{3/2} (\sigma/V)_{0.2}^2 f_{\text{dis},4}^{-1}$$

into the inner 100 pc

3.

$$\dot{M}_{\text{gas}} \approx \dot{M}_{\text{cos-acc}} - \frac{M_{\text{gas}}}{t_{\text{dyn}}} (\epsilon_{\text{inflow}} + \epsilon_{\text{sfr}} + \epsilon_{\text{out}})$$

At $z \sim 2$

$$\dot{M}_{\text{inflow}} \approx \dot{M}_{\text{sfr}} \approx \dot{M}_{\text{out}} \approx \frac{1}{3} \dot{M}_{\text{cos-acc}}$$

Bouche et al 10; Krumholz, Dekel 11; Dave et al 11

Isolated, gas-rich, turbulent disk - giant clumps - migration - bulge

Formation of an exponential spiral disk
and a central bulge

from the evolution of a gas-rich primordial disk
evolving through a clumpy phase

Noguchi 99; Immeli et al. 04; Bournaud, Elmegreen, Elmegreen 06, 08

Clump Formation & Migration

Torques in Simulated Disks

Bournaud, Dekel et al. 2011 Isolated disk at 1-pc res

Inflow in an unstable disk is not limited to clump migration, and it occurs even if clumps are disrupted, and involves stars

Formation of Spheroid by Disk Instability

Bulge~Disk in Steady State

Bulge - Black Hole - AGN

Bournaud, Dekel et al. (+simulations)

At $z \sim 2$, $M_{\text{bar}} \sim 10^{11} M_{\odot}$
inflow $\sim 20 M_{\odot} \text{yr}^{-1}$ into the inner disk

$M_{\text{BH}} - \sigma$ relation $\rightarrow 0.003 \times \text{Inflow}$ accretes onto BH

$M_{\text{bulge}} \sim M_{\text{disk}} \sim 5 \times 10^{10} M_{\odot}$ $M_{\text{BH}} \sim 10^8 M_{\odot}$

Classical bulge, $n \sim 3$, compact

$\langle \text{accretion} \rangle \sim 2\%$ Eddington, $\langle L_x \rangle \sim 10^{42-43} \text{ erg s}^{-1}$
Short brighter episodes due to clump coalescence

Gas column density $\sim 10^{23-24} \text{ cm}^{-2}$ can **obscure AGN**

Similar to major mergers, but more abundant

At $z > 6$: inflow in the disk allows Eddington accretion onto the BH
By $z \sim 6$ grow $M_{\text{BH}} \sim 10^9 M_{\odot}$ from a seed $\sim 5 \times 10^4 M_{\odot}$ at $z \sim 10$

Conclusions

High- z galaxies are fed by cold streams from the cosmic web, including mergers. The streams are co-planar to $>5R_{\text{vir}}$, embedded in a pancake, and penetrate into the inner halo. Inflow is 70% in streams (92% in 3), 20% in pancakes

Streams transport AM, mostly through one dominant stream. The disk orientation is only weakly correlated with AM at R_{vir} : AM is exchanged in the disk vicinity

Wide-angle outflows are in harmony with the dense inflowing streams

The cold streams are observable in emission (LAB) and in absorption (LLS, DLAS), but low sky coverage and low metallicity.

SFR \sim instreaming rate at $z < 2 \rightarrow$ high SFR at $z \sim 2$.

SFR is suppressed at $z \gg 2$, e.g. by low metallicity in small galaxies \rightarrow very high gas fraction

Intense gas input \rightarrow gas-rich disks \rightarrow violent instability \rightarrow giant clumps and transient features \rightarrow self-regulated inflow $\sim 10 M_{\odot} \text{yr}^{-1}$ to the disk center \rightarrow compact classical bulge, BH, AGN, obscuration

Rotating Clumps

Ceverino, Dekel, Bournaud, Burkert, Genzel, Primack 2011

ART, resolution 35-70 pc, 5 galaxies, $z=3-2$, 77 clumps

Non-rotating Extreme Clumps?

Observed (0.2''): $M_c \sim 10^{10} M_\odot \sim 0.25 M_d$, $R_c \sim \text{kpc}$,
no rotation signal, outflows

Origin?

- Toomre in-situ clumps: $M_c/M_d \sim 0.03$
- In-situ merged clumps? $M_c/M_d \sim 0.06$, 1/3 half-rotating
- Ex-situ merged galaxies? $M_c/M_d \sim 0.1$, can be non-rotating

- Disrupting clumps? If $\Sigma > 5 \times 10^3 M_\odot \text{pc}^{-2}$ then rad force $\gg L/c$
- Tilted clumps?
- Rotation unresolved?

Clump Survival, Momentum-driven Outflows

$$t_{\text{migration}} \approx 250 \text{ Gyr} \approx 1.3 t_{\text{orbit}}$$

Dekel, Sari, Ceverino 09
Ceverino, Dekel, Bournaud 10

Typical clumps complete their migration,
Extreme clumps disrupt

Krumholz & Dekel 10

$$1 - \epsilon_* \approx 0.07 f_{\text{trap},3} \epsilon_{\text{ff},0.01} V_{c,135}^{-1}$$

$$\text{force} = f_{\text{trap}} L/c$$

Typical outflows may be momentum driven.
Extreme outflows need $f_{\text{trap}} \gg 1$ ($\Sigma > 5000 M_{\odot} \text{pc}^{-2}$)
or $\epsilon_{\text{ff}} \sim 0.1$

stars/initial gas

$$\text{SFR}/(M_{\text{gas}}/t_{\text{ff}})$$

$$M_c = 4 \times 10^9 M_{\odot}, R_c = 1 \text{ kpc}, t_{\text{ff}} = 8 \text{ Myr}$$

Conclusion I

Metallicity has a major role in galaxy formation

$f_{H_2} \sim Z\Sigma$, Z is increasing with time and mass
→ quenching of SFR at $z > 2$ in $M < 10^{11} M_{\odot}$

At $z > 2$, SFR cannot catch up with the accretion + Z is low
→ in a growing galaxy SFR is rising faster than the AcR
 $SFR \sim \exp(-0.6z)$, $M_* \sim \exp(-0.65z)$

Cosmic SFR density rise ($z > 2$) and fall ($z < 1$)

Effective SFR in a narrow mass band $10^{11} - 2 \times 10^{12} M_{\odot}$ (not sharp cutoffs)

At $z > 4$, Z quenching → ex-situ > in-situ stars + $M_g \gg M_*$
→ sSFR plateau at $z = 2 - 8$

At $z > 4$, non-ejective Z quenching → gas accumulates
→ high SFR at $z = 1 - 2$, $SFR > AcR$

Many other implications: extended disks, less bulge, Low SFR in DLAS, etc.

Conclusion II

The streams feeding high- z galaxies tend to be co-planar

The plane extends to $\sim 5R_{\text{vir}}$, and penetrates into the halo

The streams are embedded in a pancake of low entropy

Inflow: 70% in streams (95% in 3), 20% in pancakes

The stream plane and AM at R_{vir} are uncorrelated with the disk:
AM is transferred in the larger disk vicinity

Wide-angle outflows seem to be in harmony with the dense inflowing streams

Conclusion III

Simulated clumps are in Jeans equilibrium, supported by rotation with some dispersion, consistent with simple theory & AM conservation.

Many clumps are highly tilted with respect to the disk

Beam smearing $>0.1''$ reduces the rotation signal to small values, consistent with typical observed clumps

Retrograde merging galaxies can be seen as disk giant clumps with no rotation signal

Typical observed clumps will complete their migration before exhaustion by outflows, while extreme clumps are disrupted.

Extreme outflows can be generated by momentum-driven feedback if $\Sigma > 5000 M_{\odot} \text{pc}^{-2}$ allowing multiple scattering, or if the SFR efficiency is higher than Kennicutt

Sub-structure in the disk giant clumps

When clump substructure is resolved:
Less dissipative contraction? Angular-momentum loss?
a 20-30% effect

Caution: MW molecular clouds are not spin-supported

Bournaud, Teyssier AMR 2 pc resolution
