

The Formation of Massive, Compact Galaxies at $z = 2$ in the Illustris Simulation

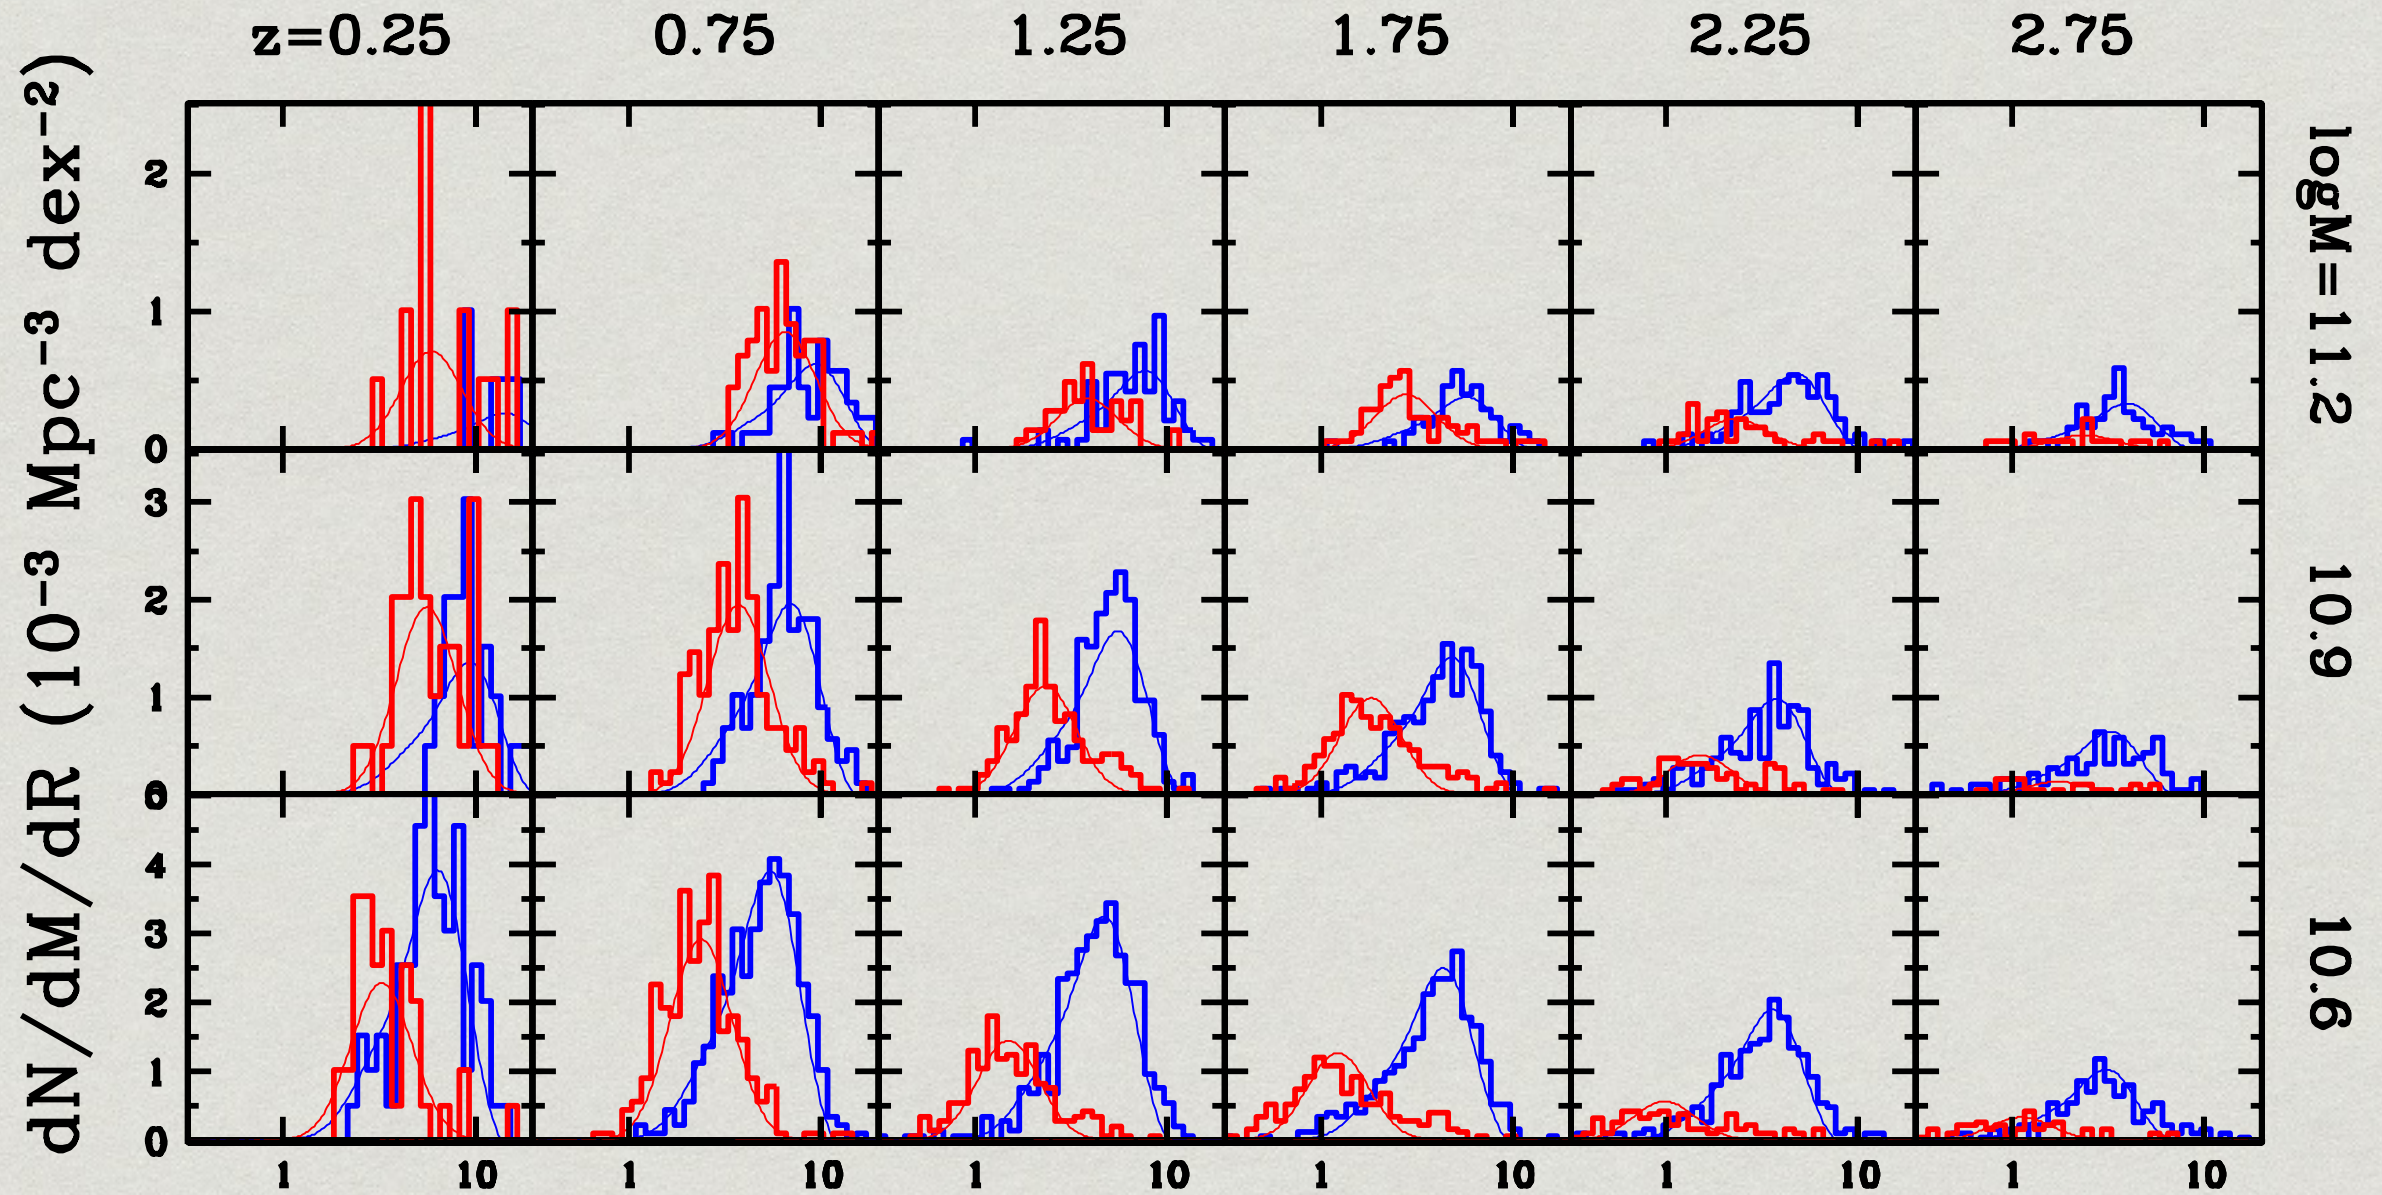

Sarah Wellons
Harvard/CfA

In collaboration with: Paul Torrey, Chung-Pei Ma, Lars Hernquist, Mark Vogelsberger, Mariska Kriek, Pieter van Dokkum, Erica Nelson, Shy Genel + the rest of the Illustris team

Strong size evolution of quiescent galaxies

van der Wel et al. 2014, 3D-HST+CANDELS

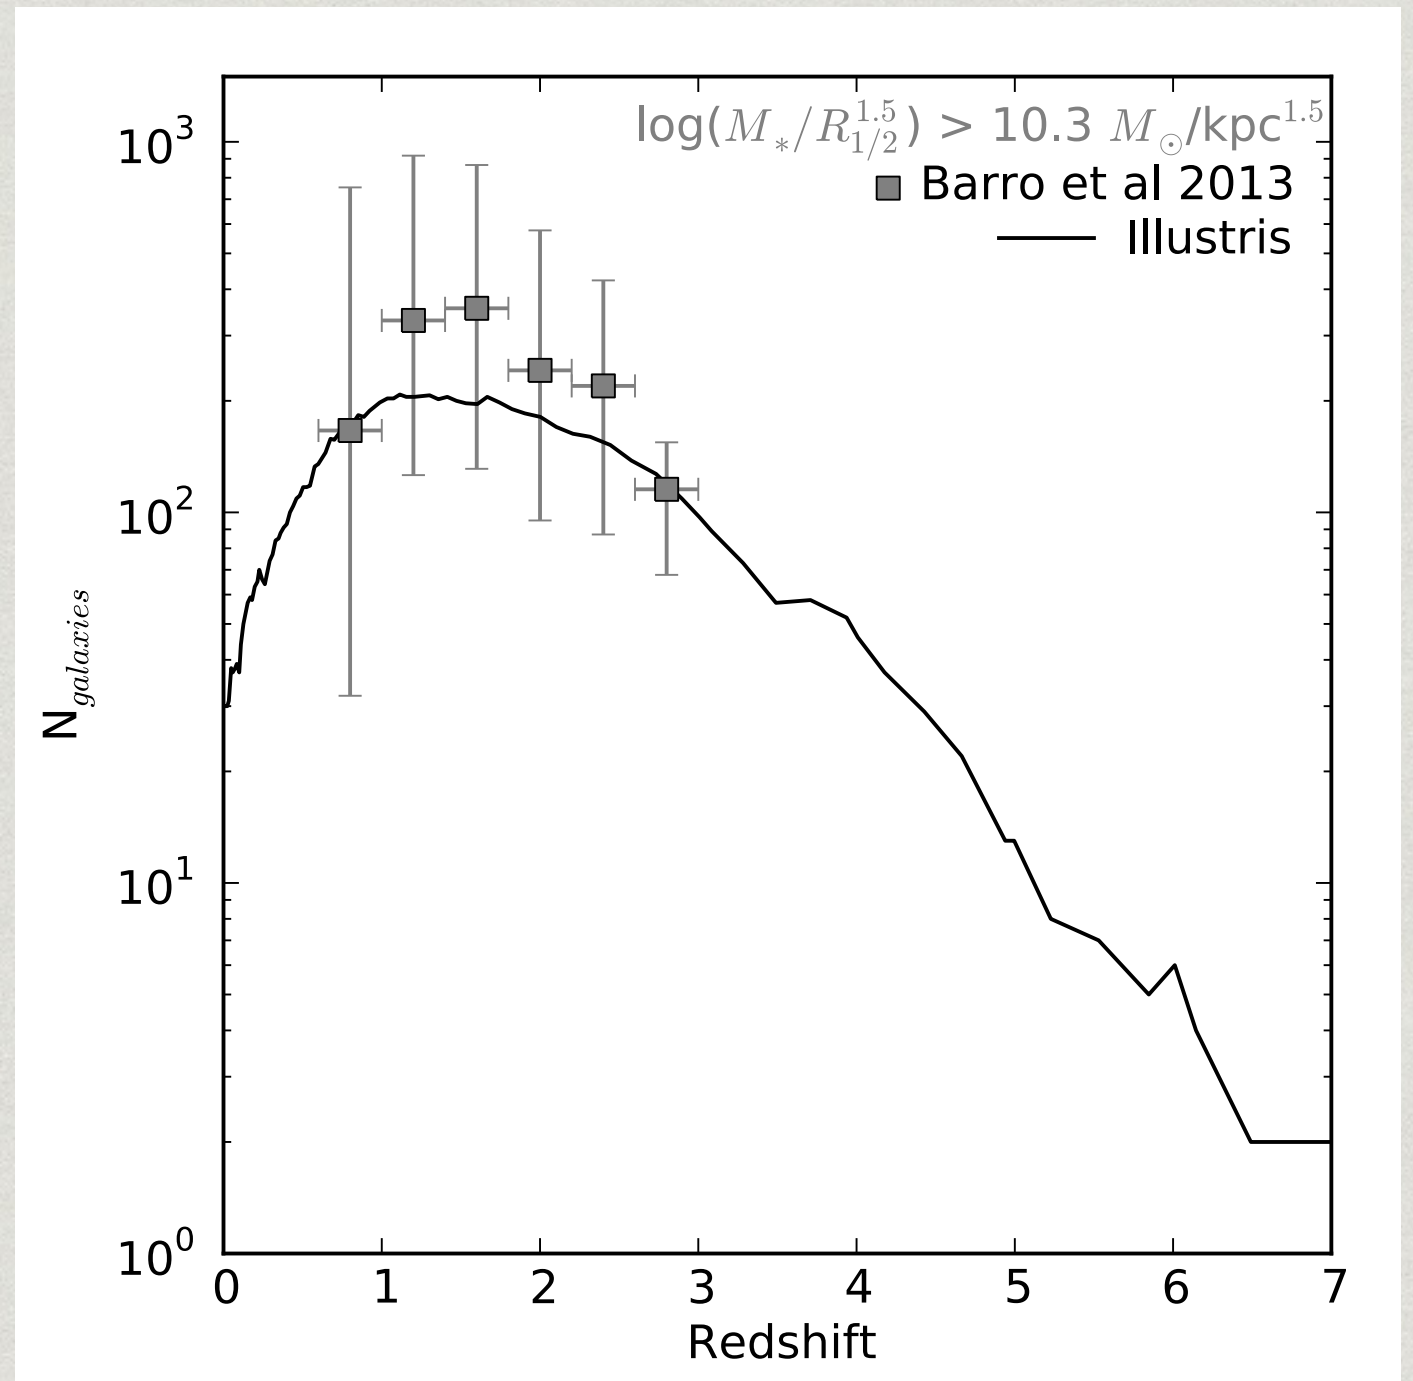

Illustris simulation

- * Simulation volume of $(106.5 \text{ Mpc})^3$
- * Baryonic resolution elements have mass $1.3 \times 10^6 M_{\odot}$
- * Gravitational softening length 0.35-0.5 kpc at $z = 2-3$
- * N-body + hydro (using moving-mesh code AREPO)
- * Includes phenomenological models for star formation and evolution, gas cooling, stellar and black hole feedback

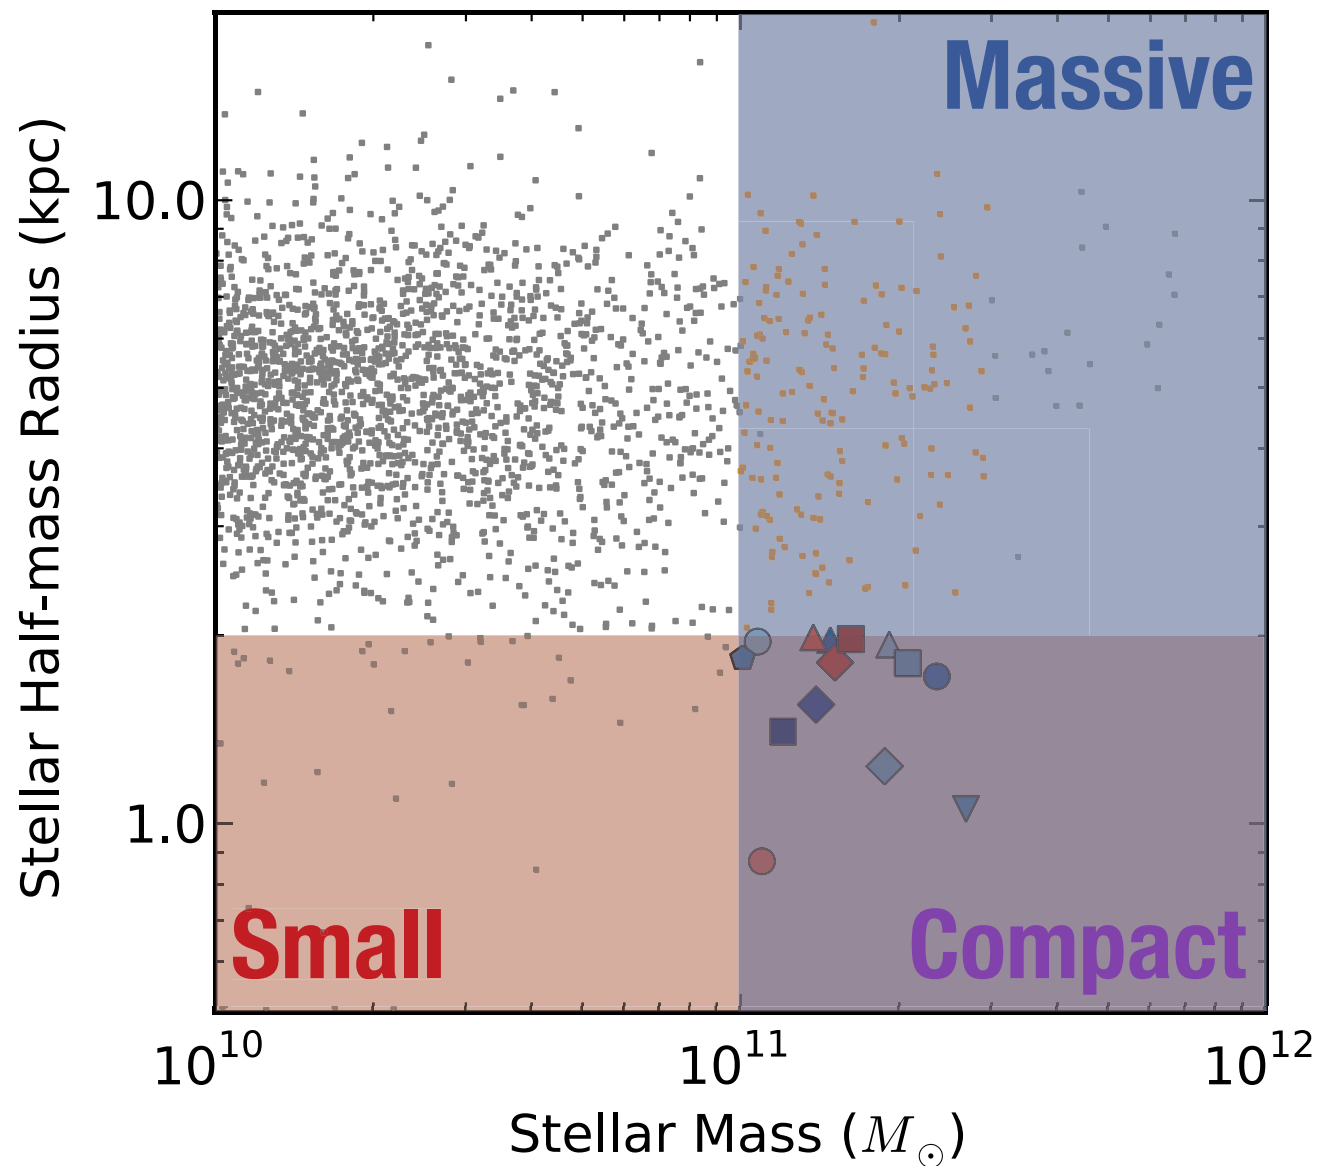

Number density evolution of compact systems

- * Abundance of compact galaxies peaks at $z = 1-2$, then drops
- * Number densities agree reasonably well with observations when same selection criteria is used

“Compact” selection criteria

Select for galaxies with:

- * stellar mass $> 10^{11} M_{\odot}$
- * half-mass radius $< 2 \text{ kpc}$

14 massive,
compact galaxies

Mock images

Compact

10 kpc

Non-Compact

Properties of compact population

High central densities

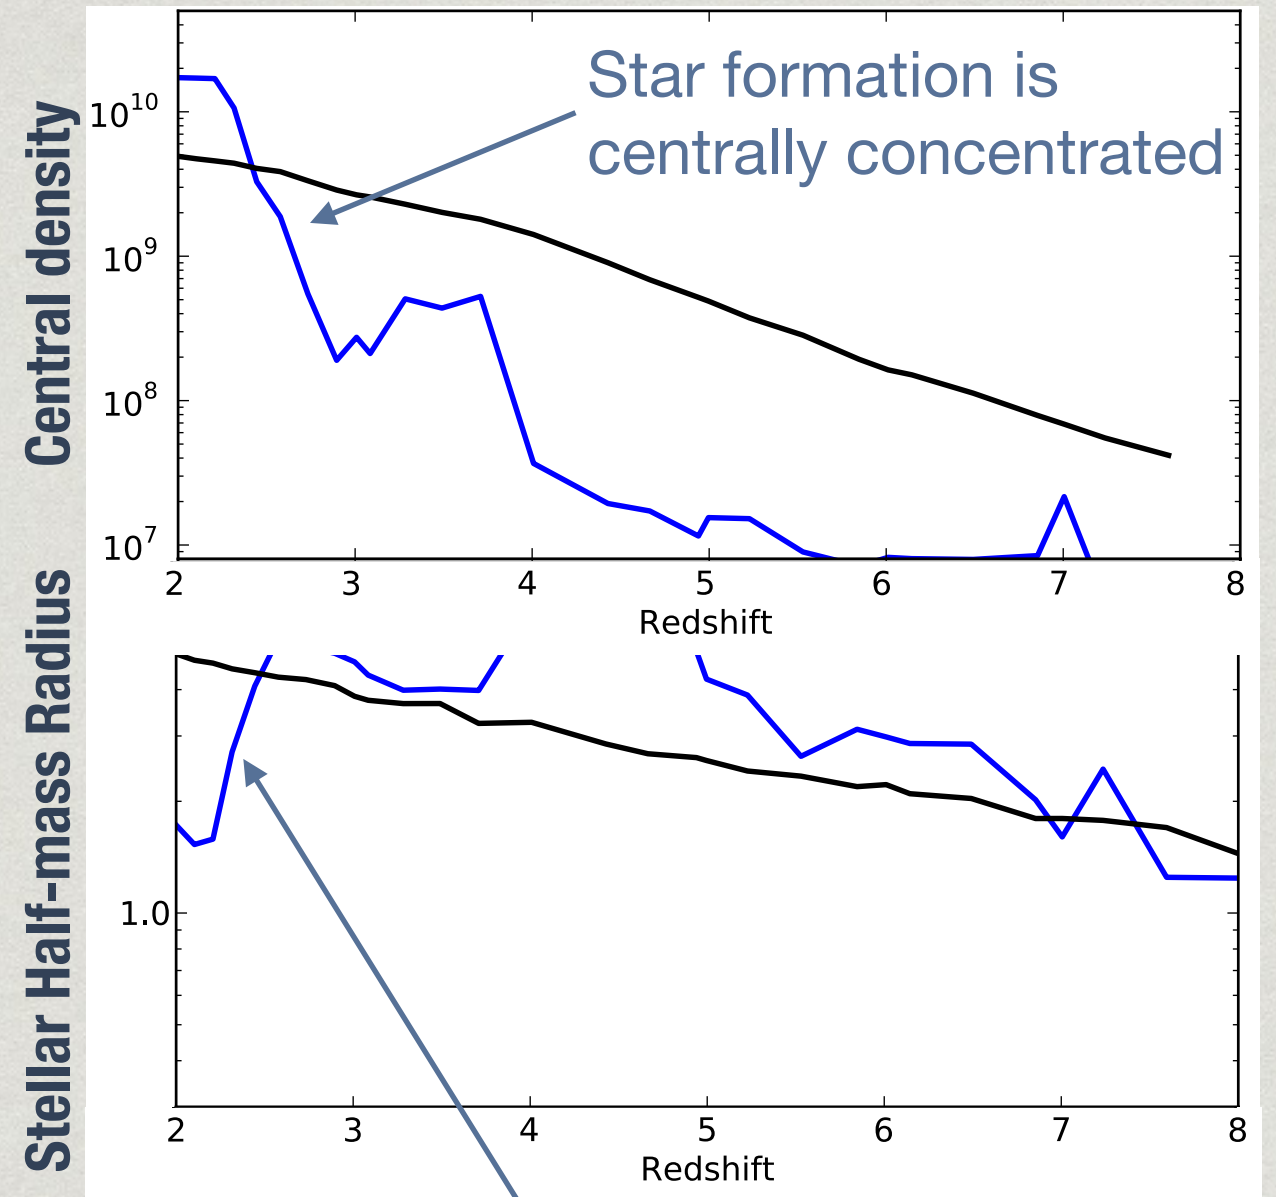

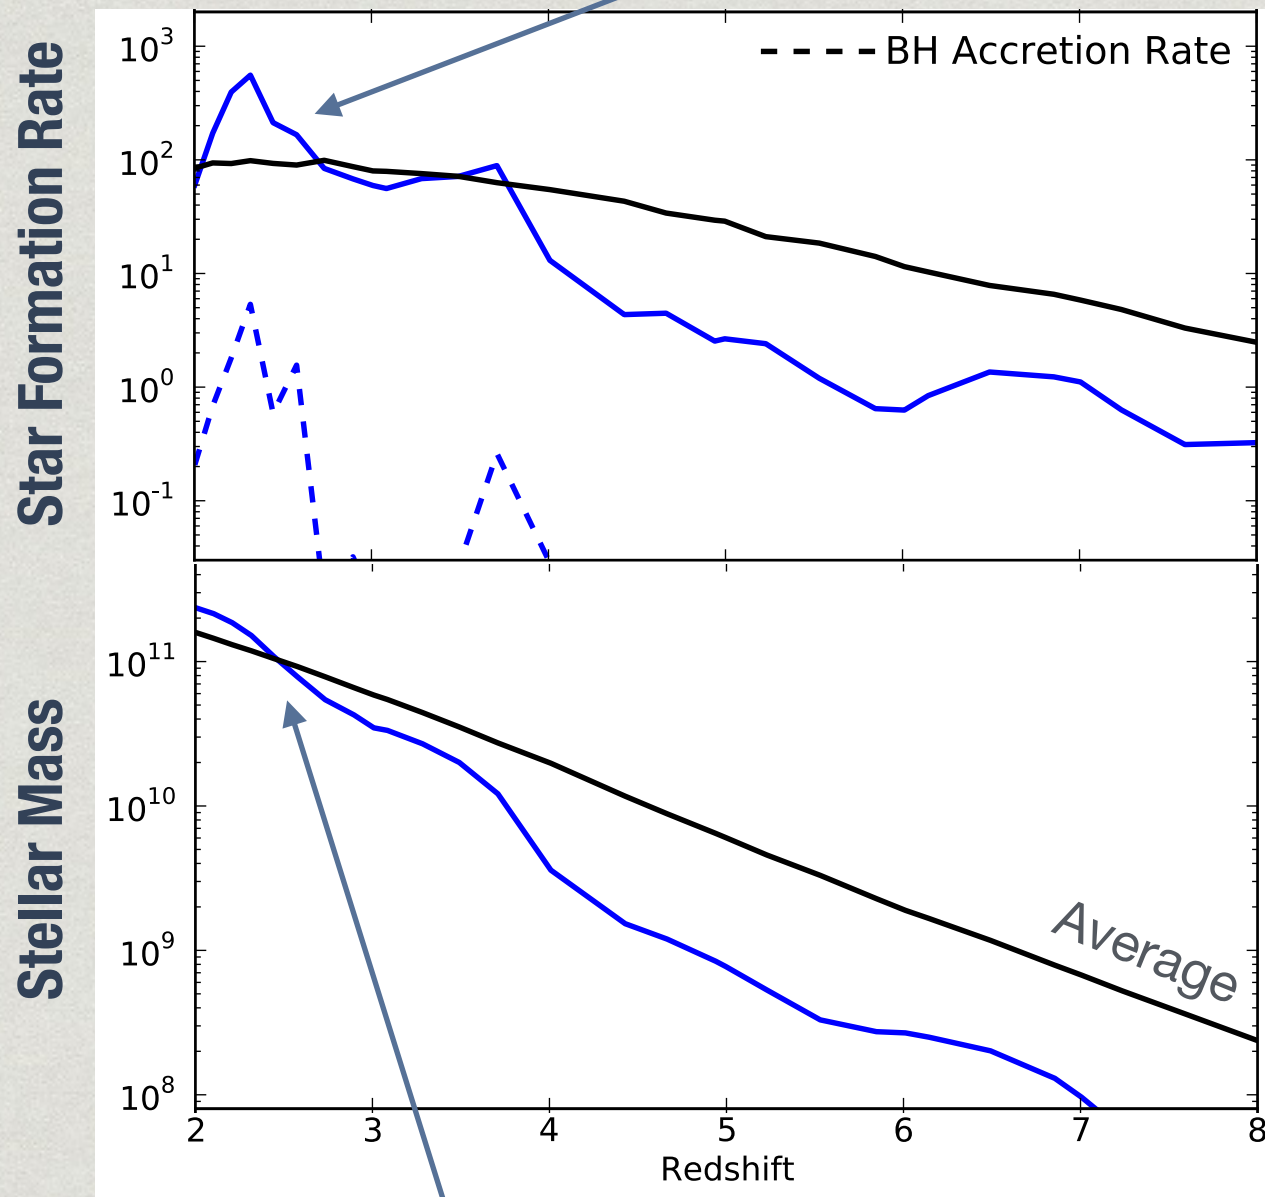

Star formation often quenched

Often redder in color

Formation channels

Example #1:

Major merger is accompanied by burst of star formation

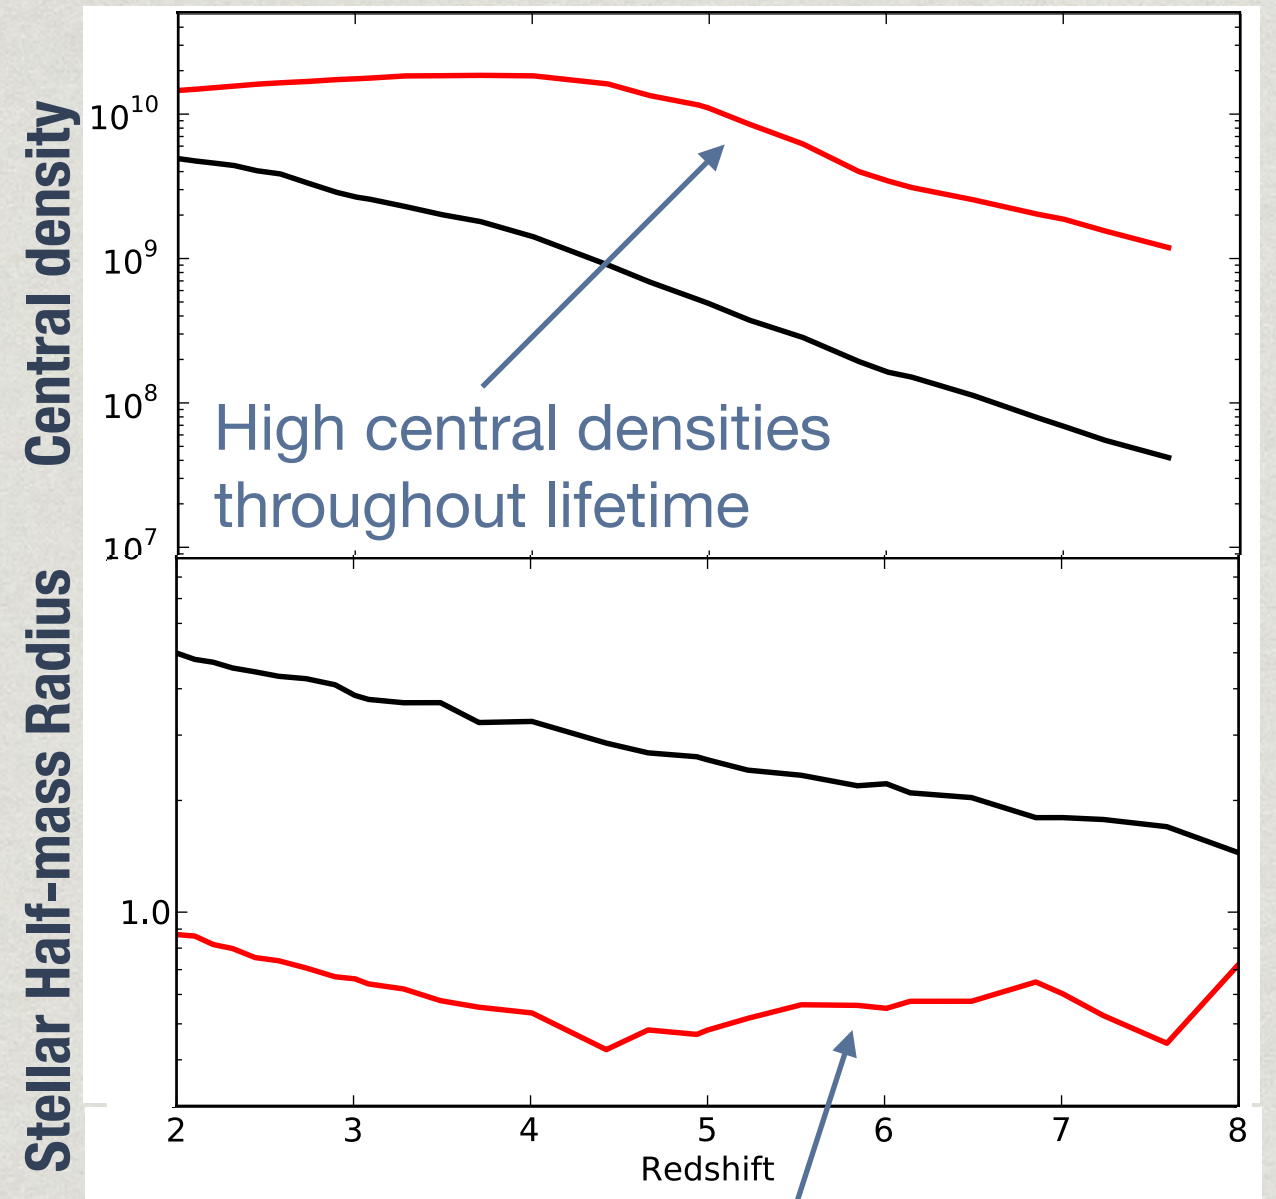

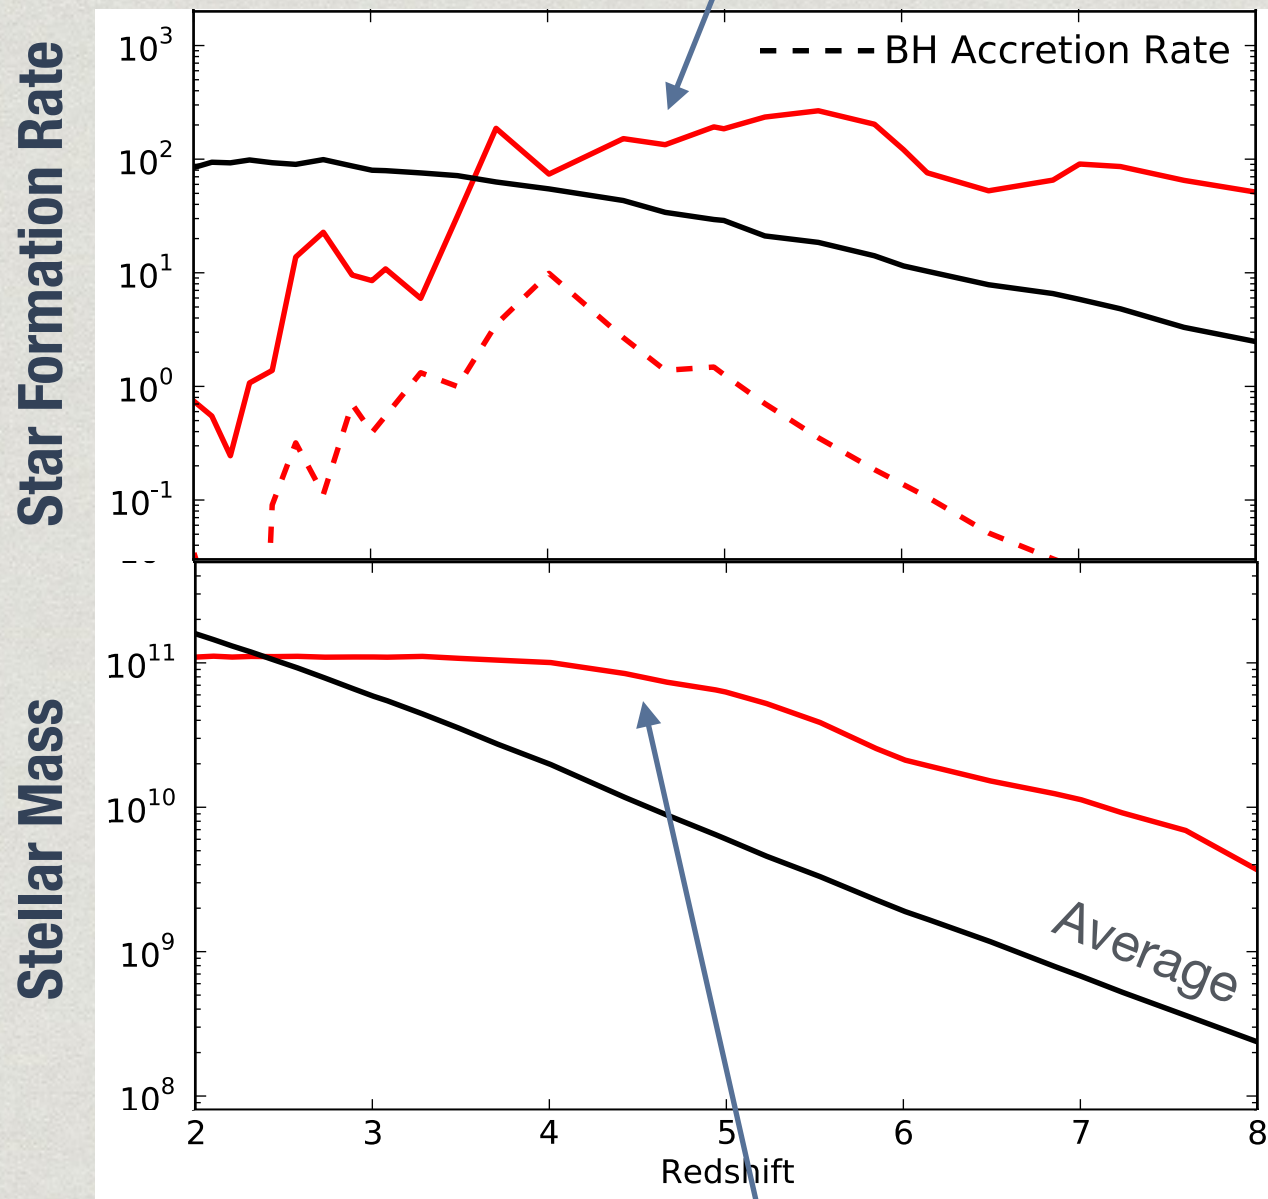

Major gas-rich merger drives intense central starburst

Increase in central density drives down half-mass radius

Formation channels

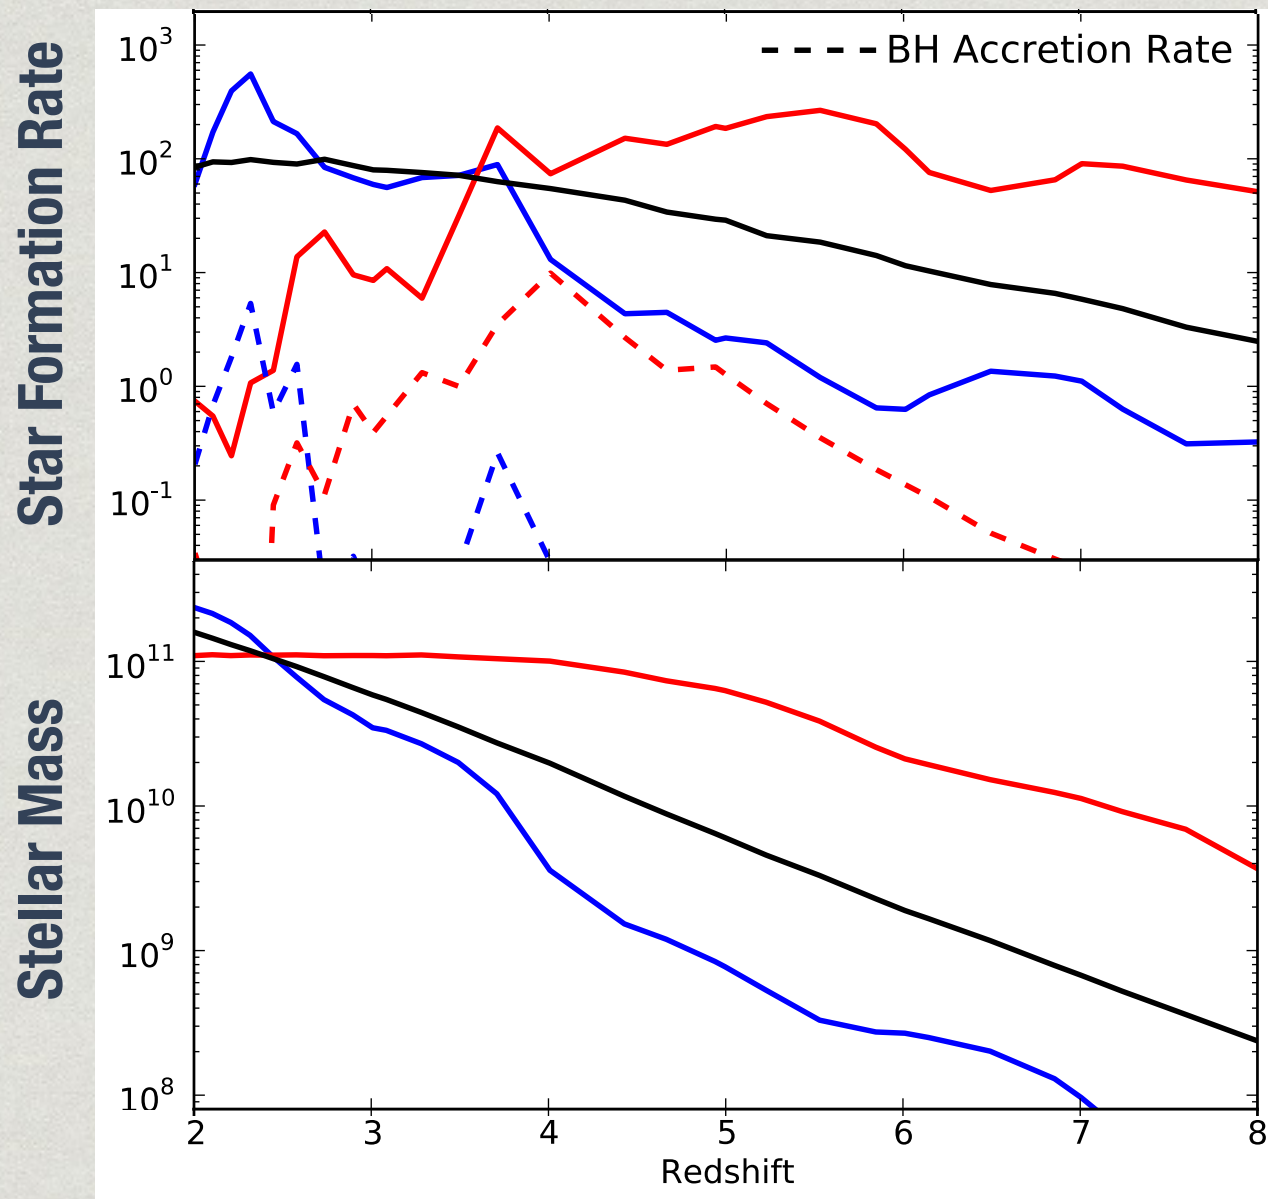

Example #2:

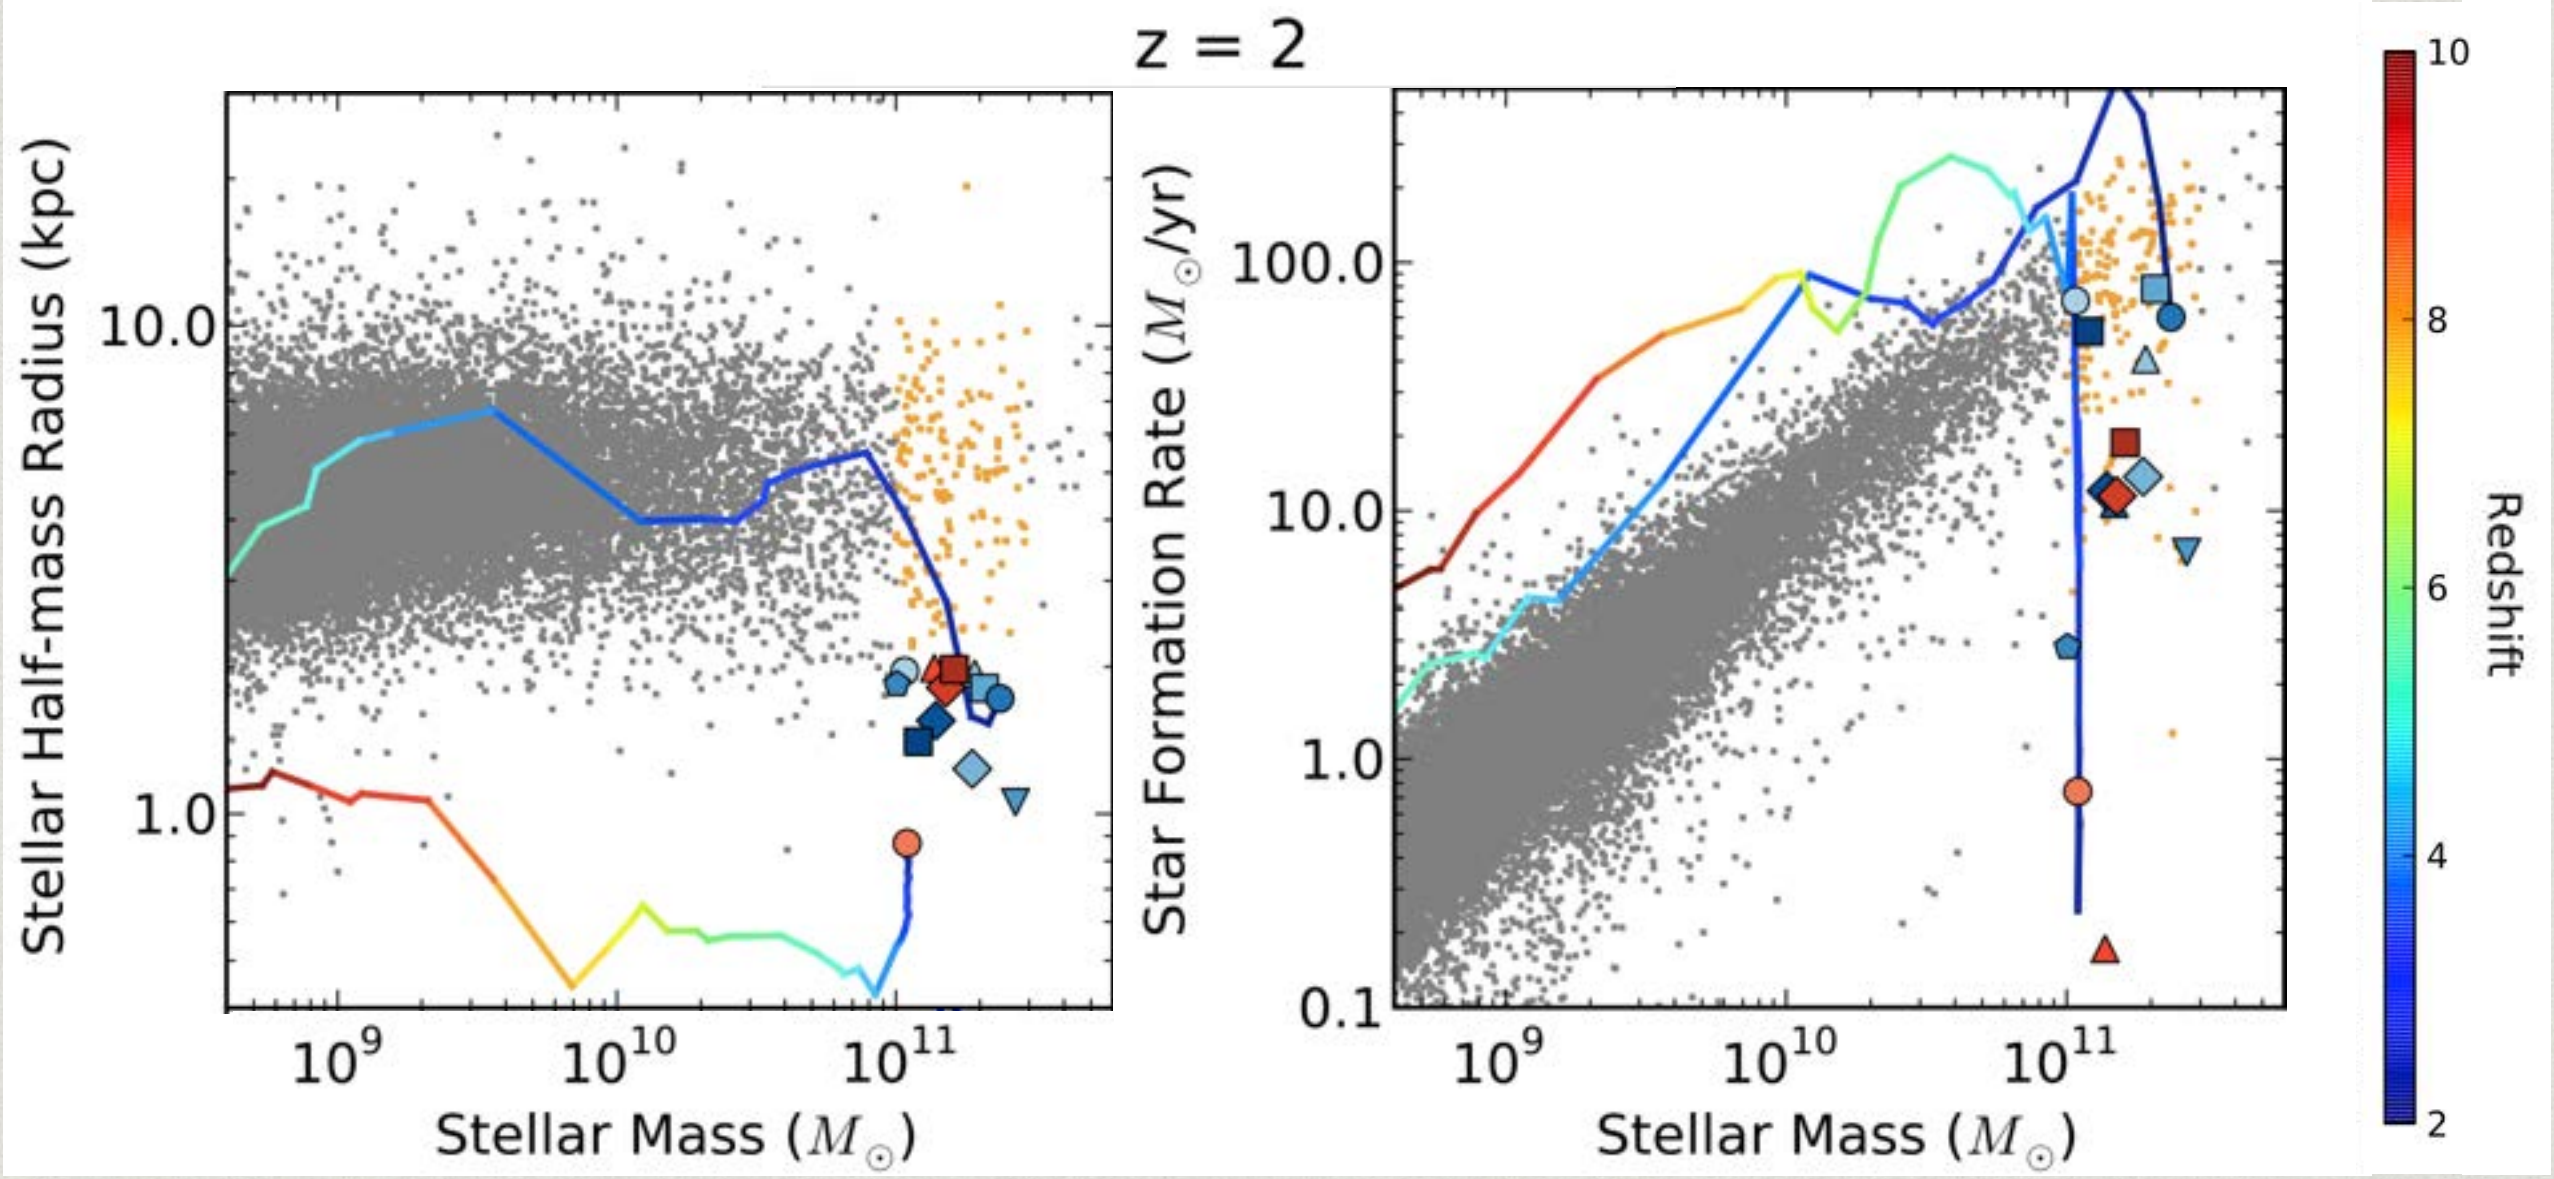

SFR an order of magnitude higher at early times, then quenches at $z=4$

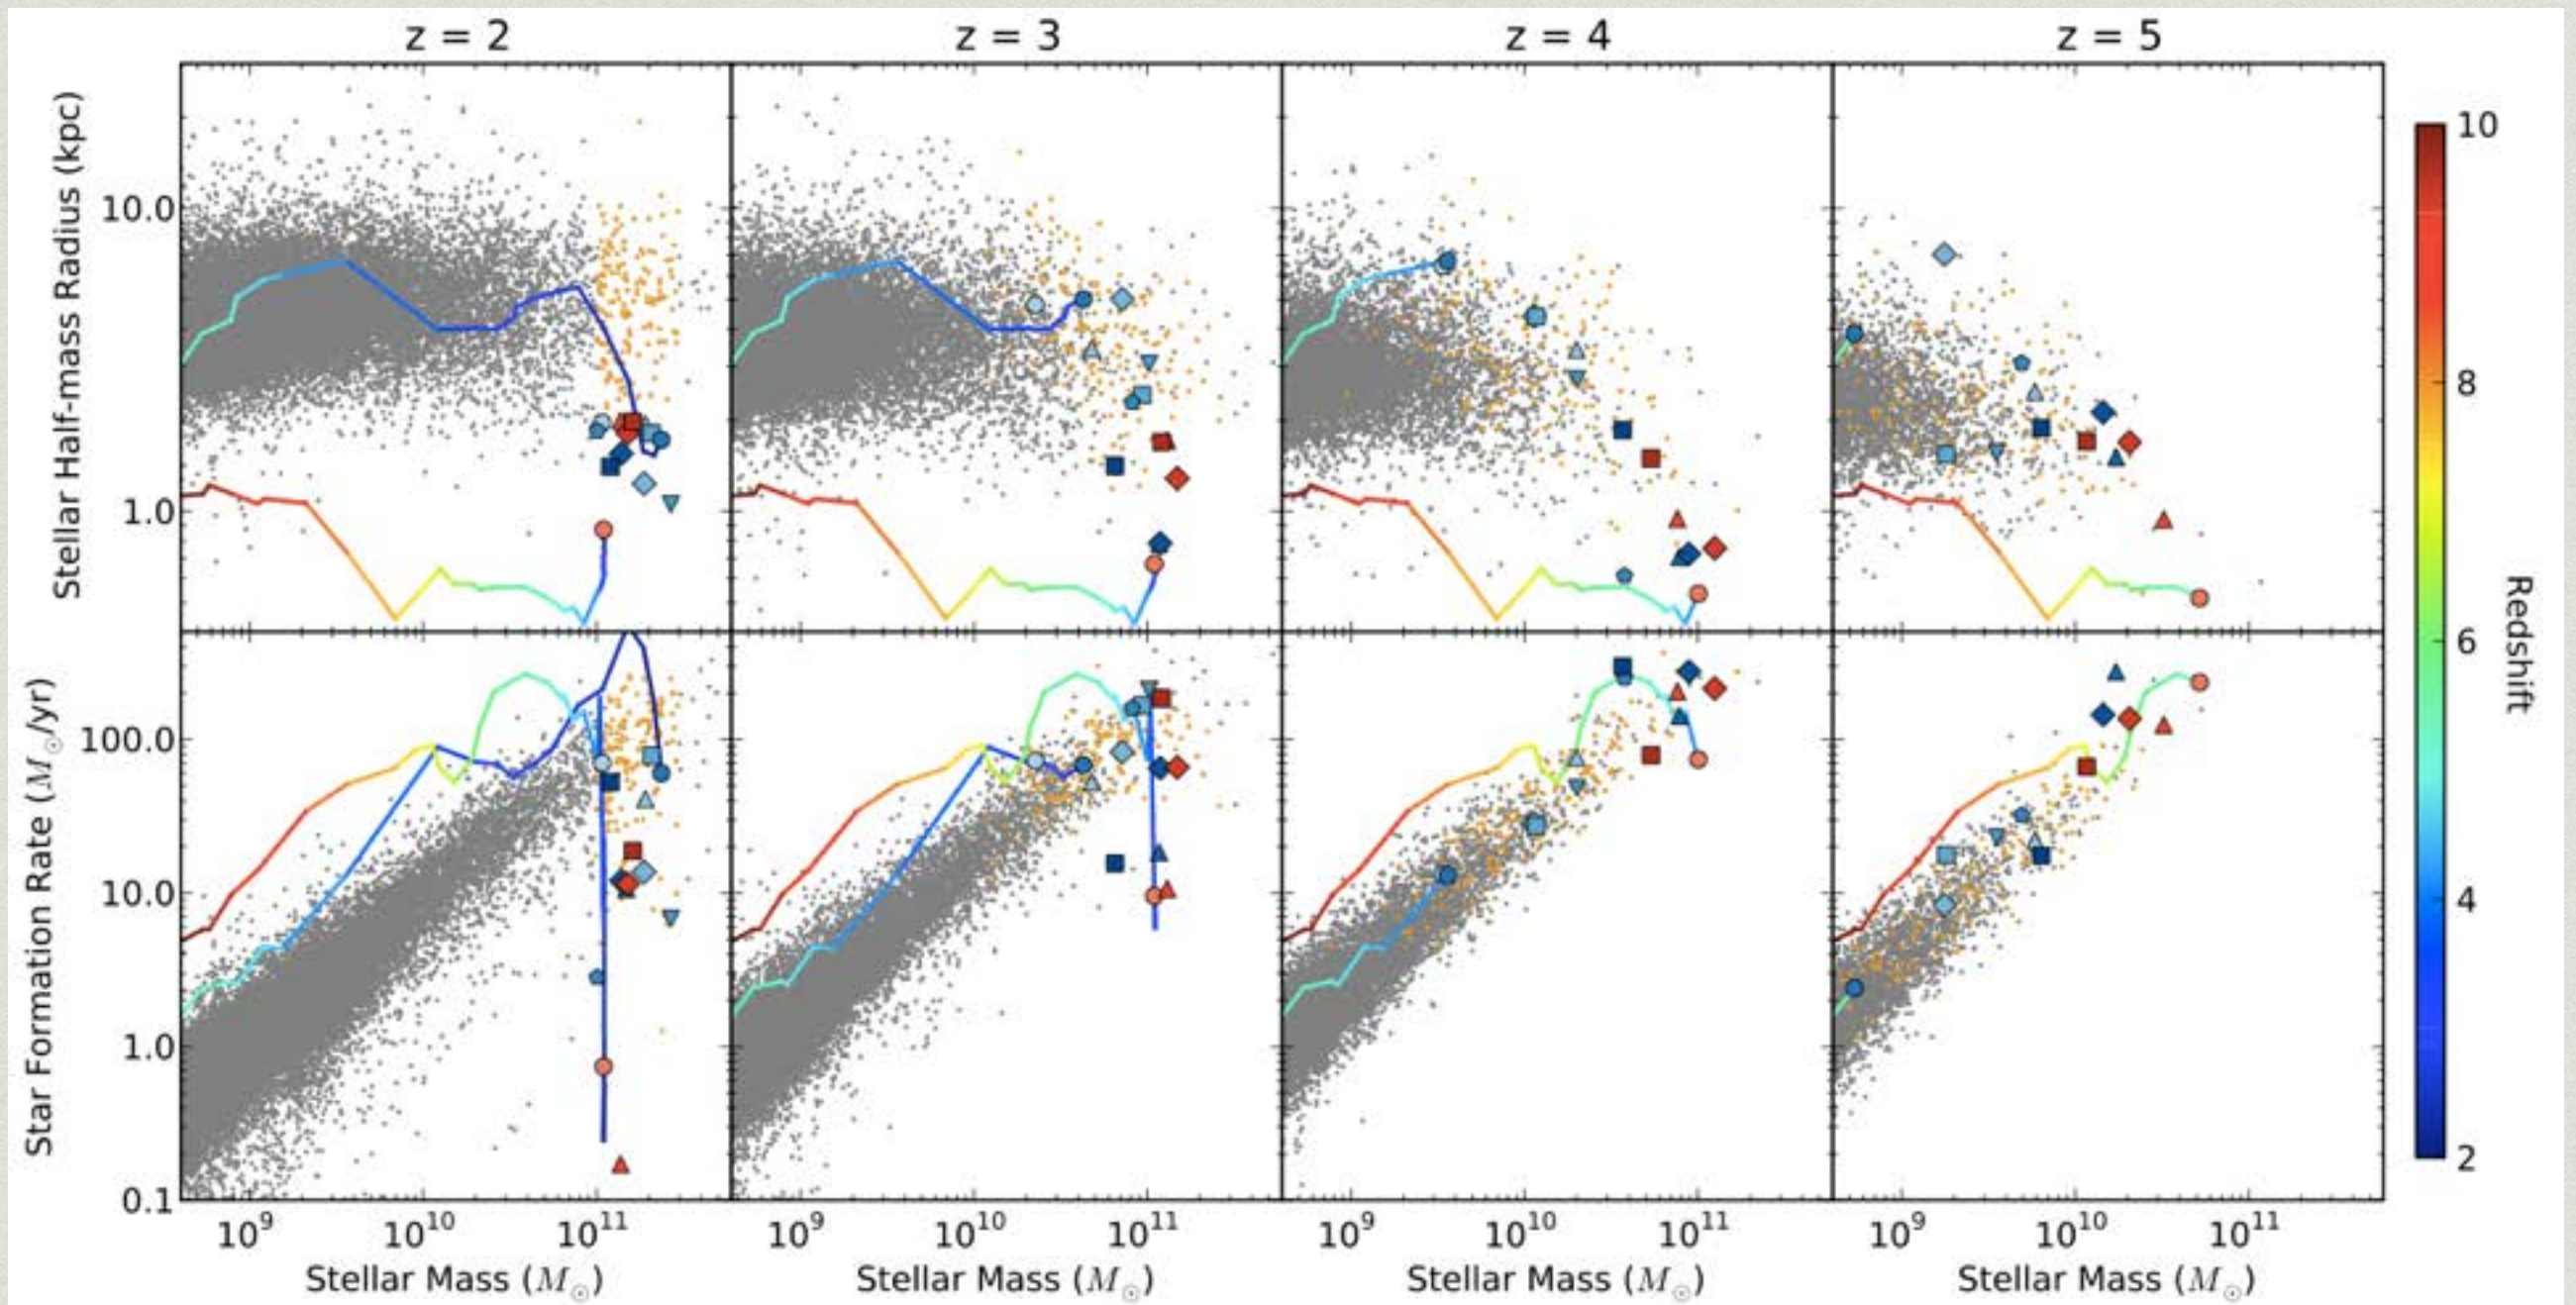

Stellar mass is assembled early and gradually **Early formation** → **small size** Forms with, and maintains, small size

Two distinct formation mechanisms: Central starbursts & Early assembly

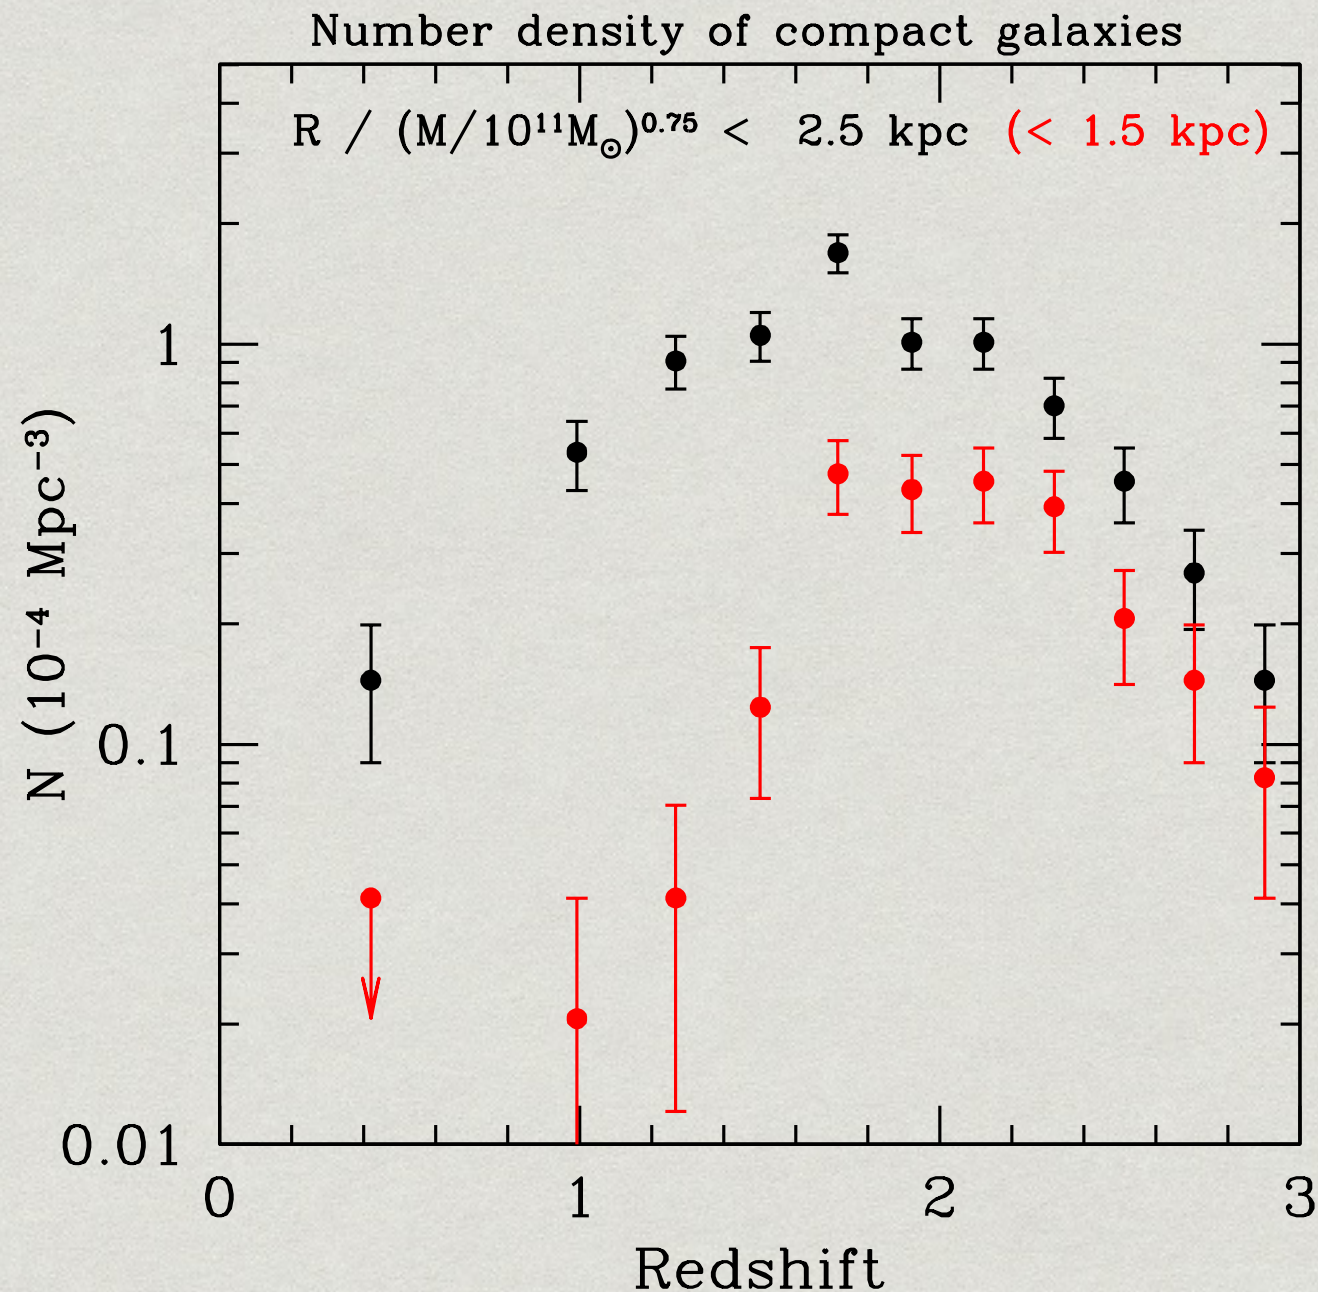

All of the 14 compact galaxies form in ways that resemble these two paths

4 early formers, 10 central starbursts

Both of these mechanisms require high-z conditions

Central starbursts:

Frequency depends on abundance of cold gas

Early formation:

Size of galaxy depends on scale factor

Number density will decrease at low redshift

Summary

- * We search in the Illustris volume for massive, compact galaxies at $z=2$
- * 14 galaxies have stellar mass $> 10^{11} M_{\odot}$ and half-mass radius < 2 kpc
- * Each galaxy formed early, experienced a central starburst, or some combination thereof
- * These formation mechanisms are most effective at high- z , leading to a decrease in number density thereafter
