

# Star Formation on Galactic Scales: Is Life Simple?

**Nick Gnedin**

THE UNIVERSITY OF  
**CHICAGO**

# Co-starring

**Robert Feldmann (Fermilab)**

**Andrey Kravtsov (Chicago)**

# Just One Question:

**Are Gods kind to us?**

# What We Know About Star Formation

Star formation correlates well with molecular gas...

$z=0$  (Bigiel et al 2011)

High  $z$  (Genzel et al 2010)

# What We Know About Star Formation

... for a simple physical reason.

(Krumholz, Leroy, McKee 2011)

# How We Actually Think About Star Formation

$$\dot{\rho}_* = \frac{\rho_{\text{H}_2}}{\tau_{\text{SF}}}$$

$$\tau_{\text{SF}} = \tau_{\text{SF}}(\rho_{\text{H}_2})$$

**Pop quiz (10 pts):** Why is this thinking wrong?

Density is only defined on a particular spatial scale.

# How We Should Think About Star Formation

- Take some spatial scale  $L$
- Average all densities on this scale - only those are meaningfully defined

$$\langle \dot{\rho}_* \rangle_L = \frac{\langle \rho_{\text{H}_2} \rangle L}{\tau_{\text{SF}}}$$

$$\tau_{\text{SF}} = \tau_{\text{SF}}(L, \langle \rho_{\text{H}_2} \rangle, \dots)$$

# Let's Think in 2D!

# Large Scales: z=0

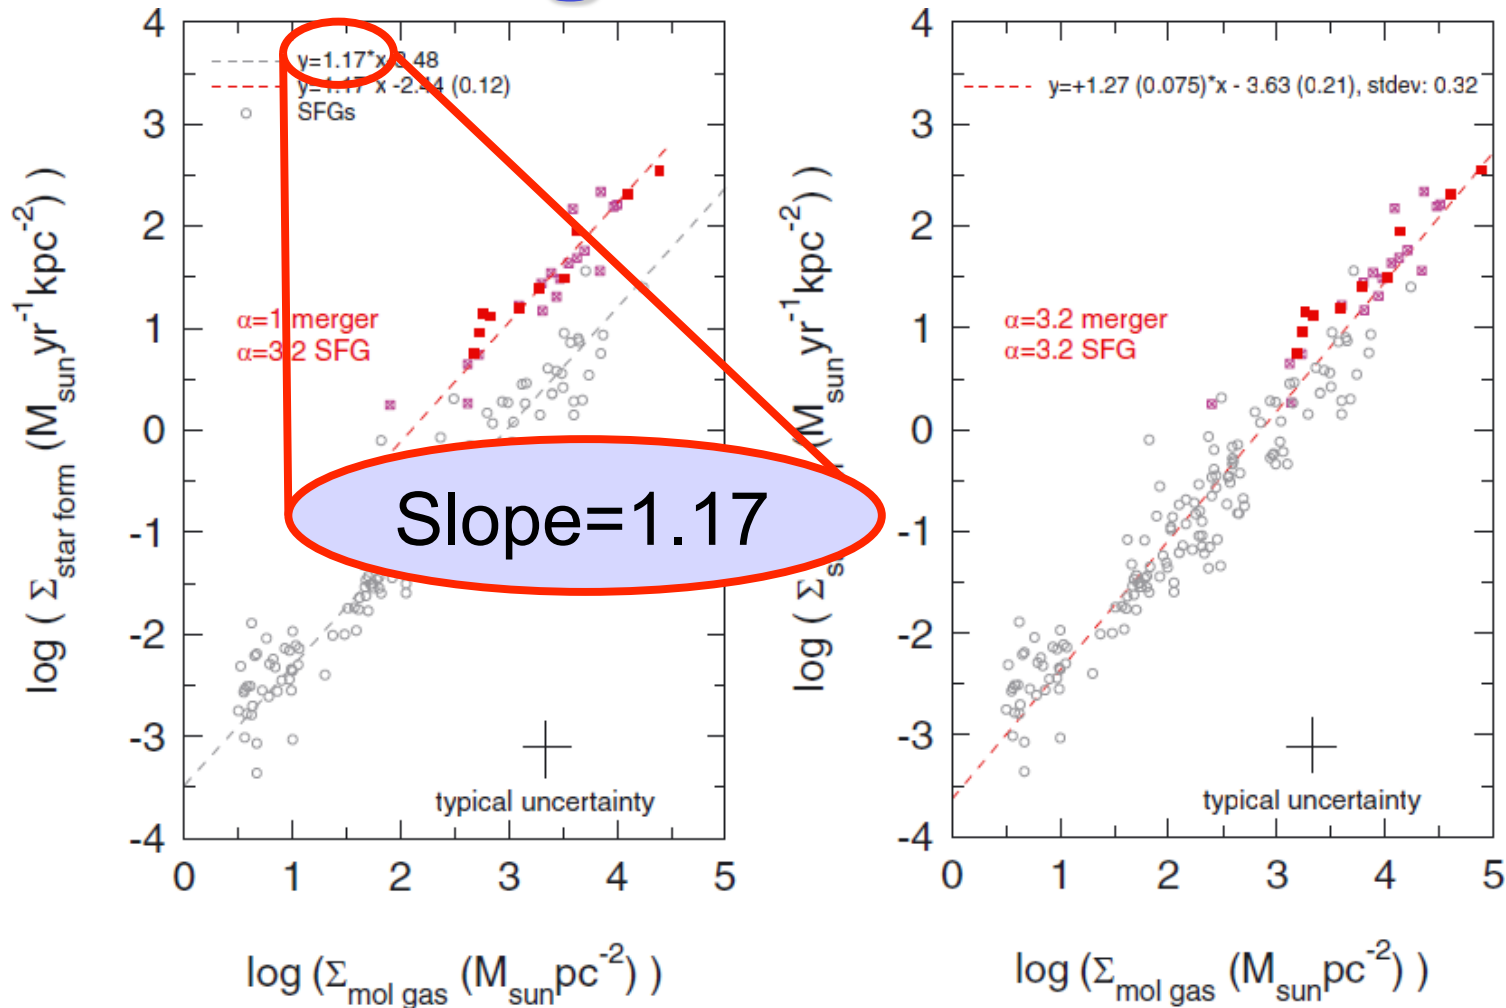

$$L \sim 500 \text{ pc}$$
$$\tau_{\text{SF}} \approx 2 \text{ Gyr}$$

- Constant time-scale
- Linear SF recipe

(Bigiel et al 2011)

# Large Scales: $z > 1$

(Genzel et al 2010)

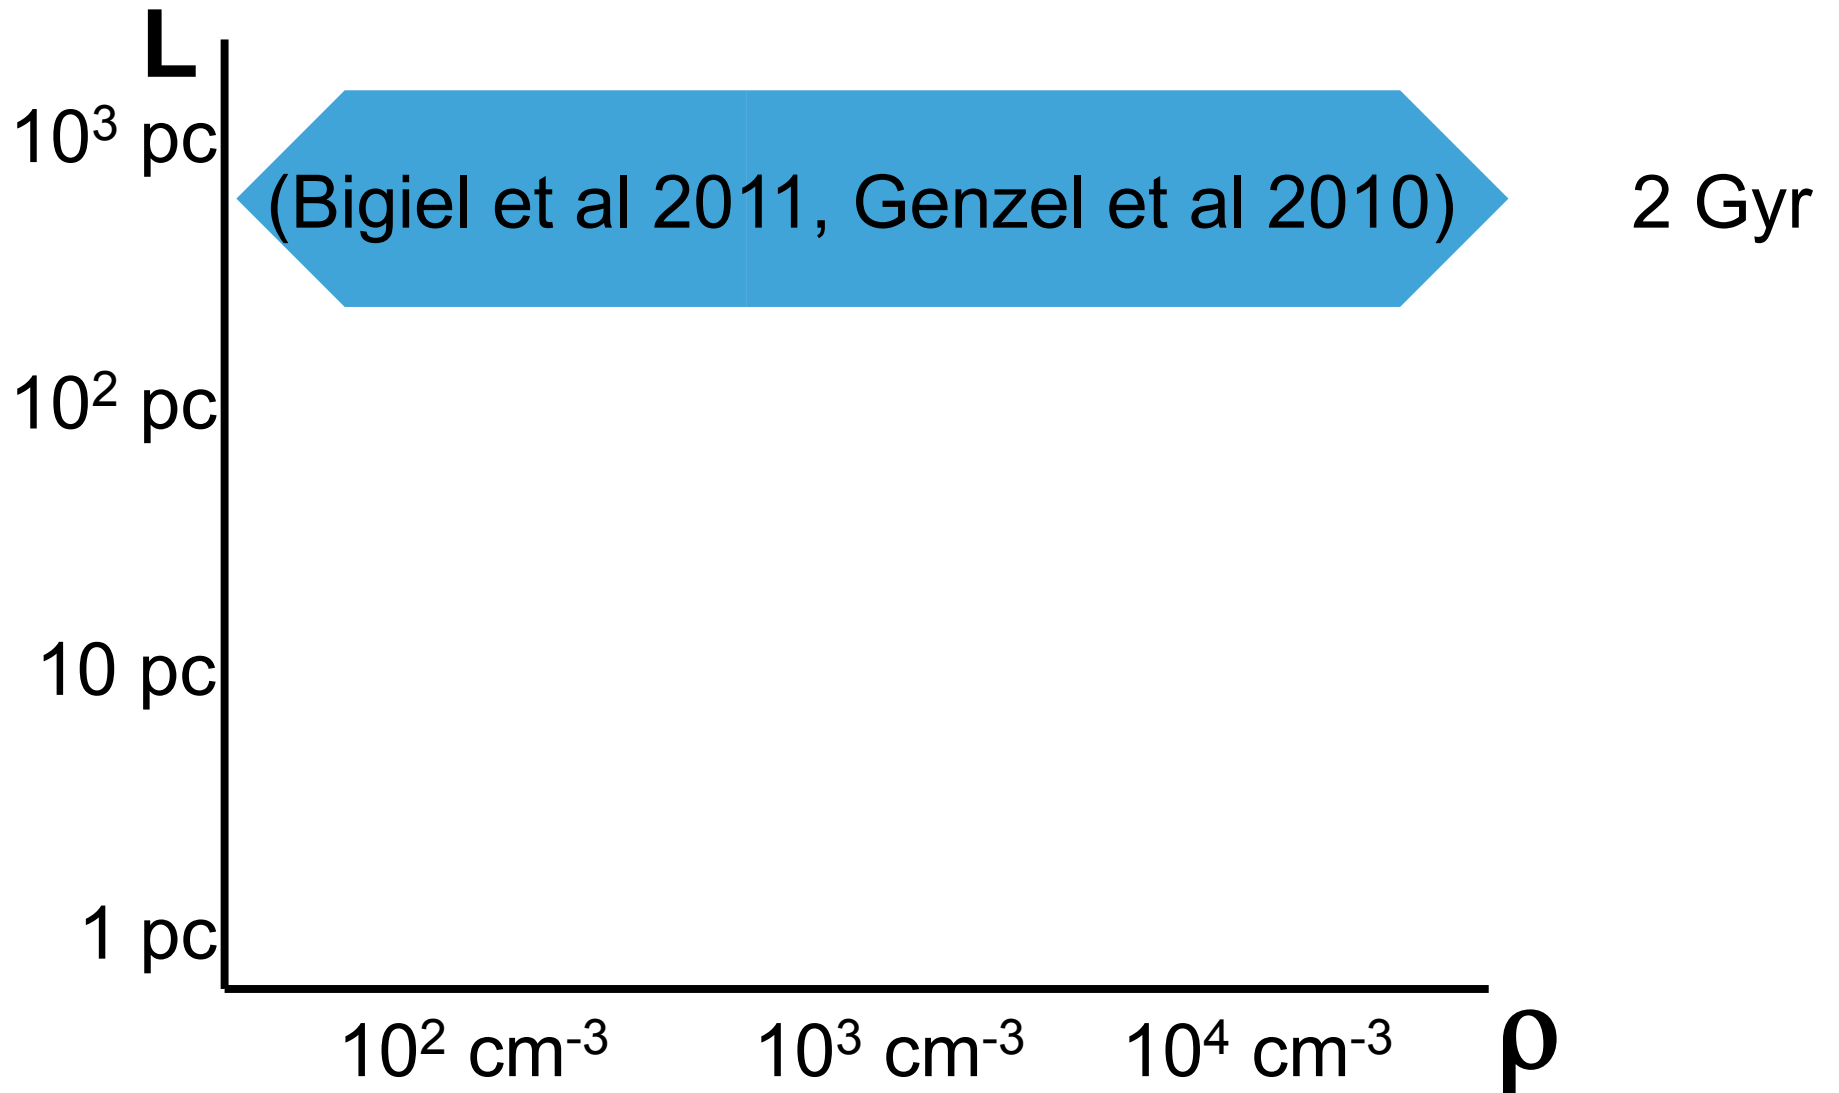

# Large Scales: $z > 1$

- X-factor **must** increase at large surface densities (unless the metallicity is very low)
- Genzel et al data **are consistent** with the constant depletion time-scale

(Feldmann, Gnedin, Kravtsov 2012)

# Let's Think in 2D!

# Let's Think in 2D!

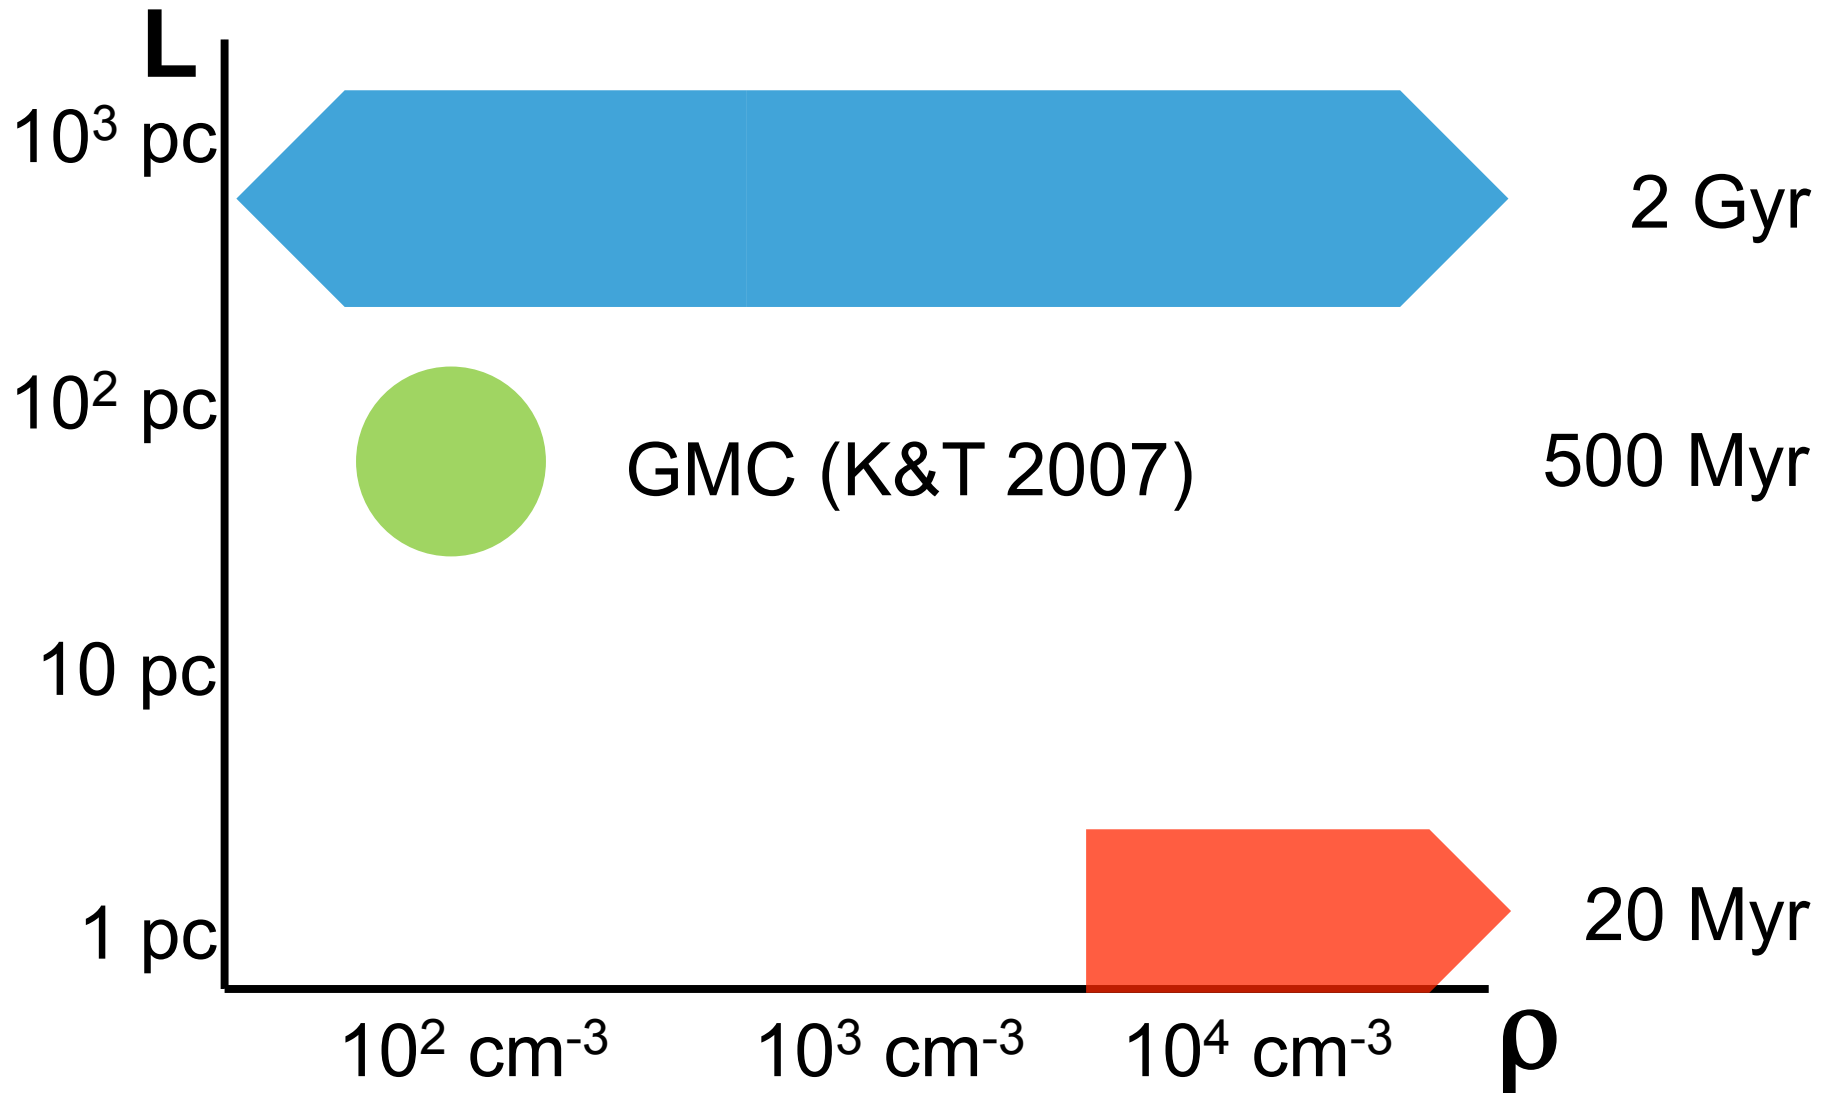

# “Don’t Be Hasty...”

Krumholz & Tan (2007):  $\tau_{\text{SF}} \propto \tau_{\text{ff}} \propto \rho^{-1/2}$

# Let's Think in 2D!

# Let's Think in 2D!

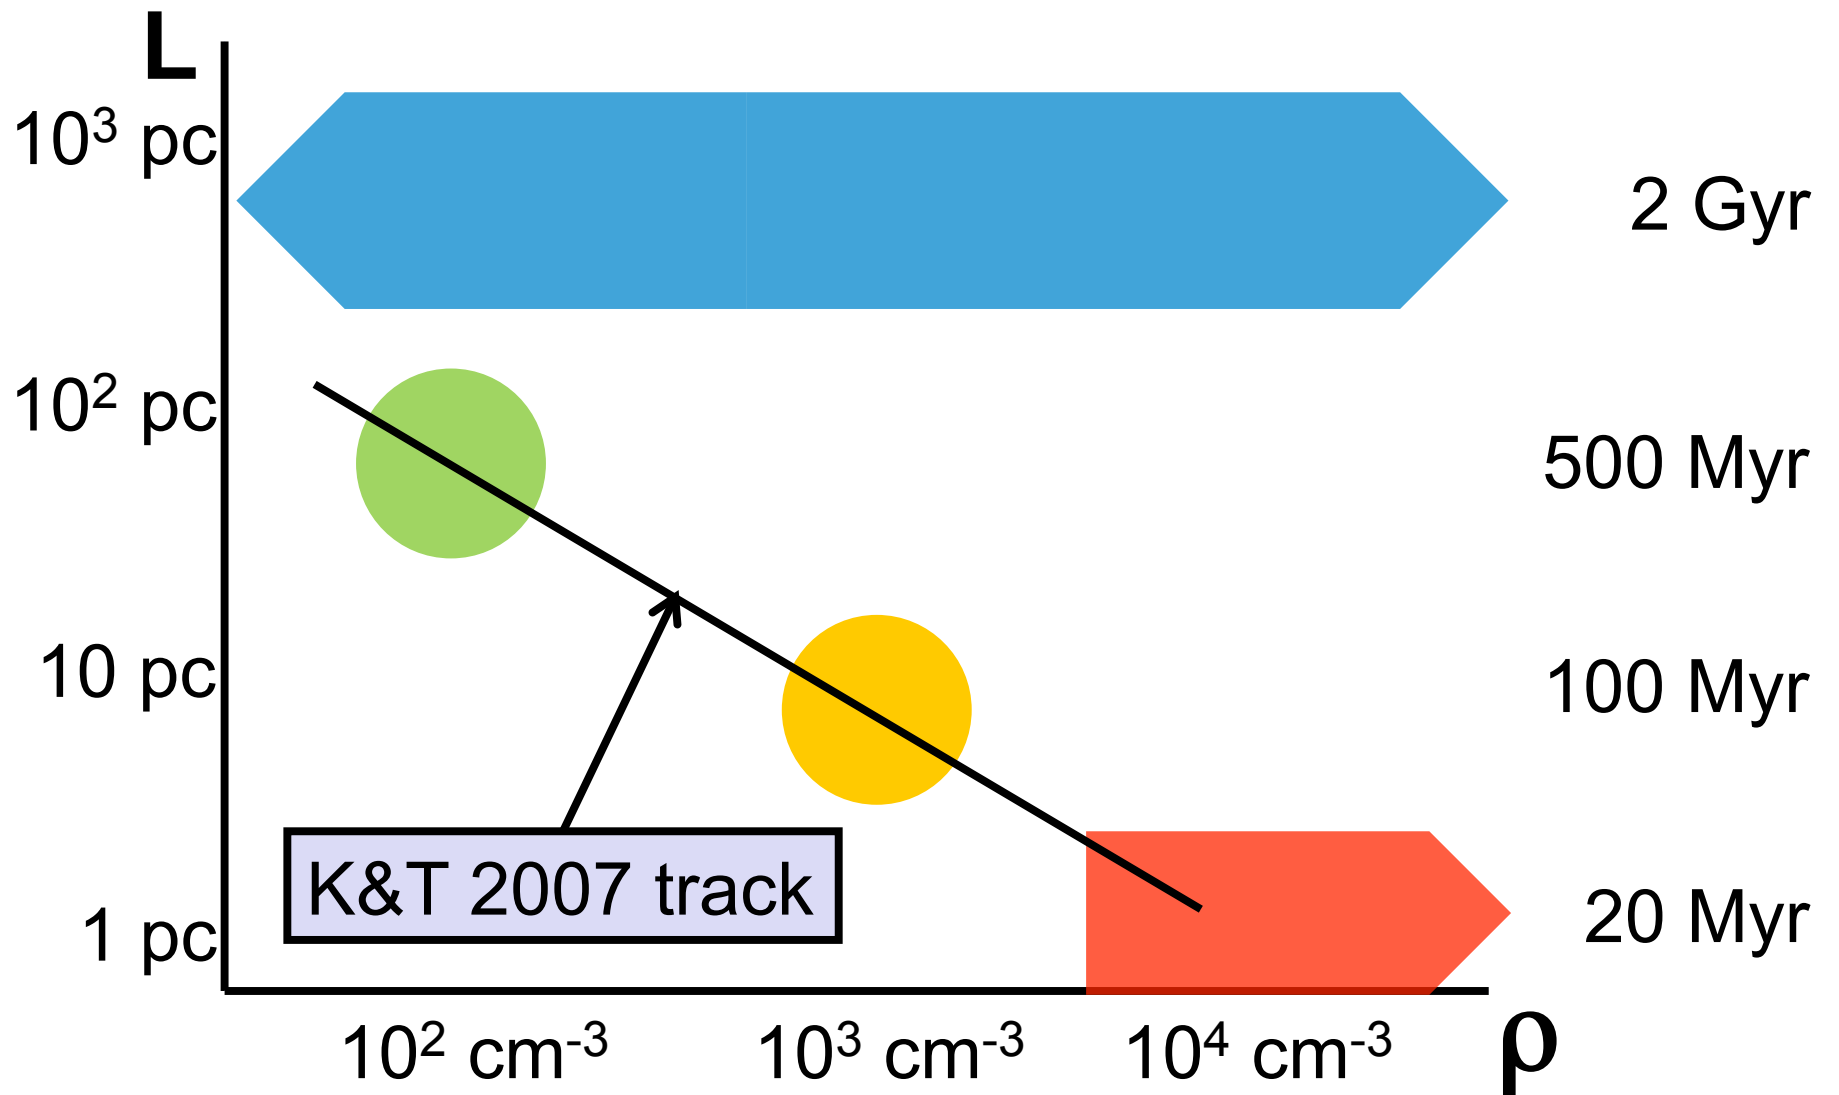

# Let's Think in 2D!

# Let's Think in 2D!

# Simple Life Idea

# Simple Life Idea

# Simple Life Idea

$$\tau_{\text{SF}}(L) \approx 2 \text{ Gyr} \times \min \left( 1, \frac{L}{100 \text{ pc}} \right)$$

May be

$$\rho_{\text{min}}(L) \approx 10/\text{cc} \times \min \left( 1, \frac{L}{100 \text{ pc}} \right)^{-1}$$

# Does It Work?

**PRELIMINARY!!!**  
**NO PHOTOGRAPHY!**

# Conclusions

- Star formation recipe depends on both **scale** and **density**:

$$\langle \dot{\rho}_* \rangle_L = \frac{\langle \rho_{\text{H}_2} \rangle_L}{\tau_{\text{SF}}}$$

- Existing data are consistent with the **linear** (in density) **average** star formation hypothesis (there must be scatter/hidden parameters, Gods are never **that** kind):

$$\tau_{\text{SF}} = \tau_{\text{SF}}(L, \langle \rho_{\text{H}_2} \rangle_L) \begin{pmatrix} \times \text{scatter} \\ \times \text{threshold} \end{pmatrix}$$

# Conclusions

- If that hypothesis is true, life becomes easier for simulators:
  - In simulations with  $\approx$  constant resolution, the SF rate is a linear function of (molecular) gas density;
  - Long consumption time-scale eliminates the need for early feedback a-la Stinson et al 2012 (gas remains as gas until  $z \sim 3$ , plenty of time to blow it out);
  - With linear SF recipe simulations numerically converge.

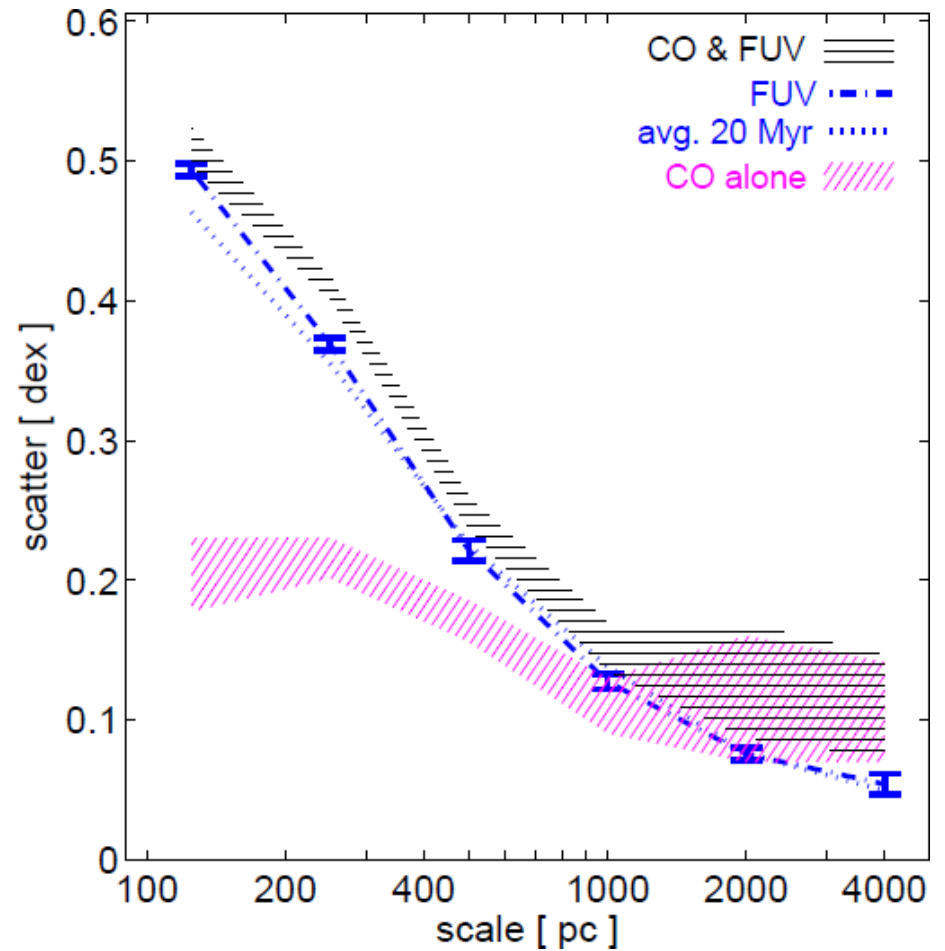

# The End

# No Scatter?

(Leroy et al 2012)

(Feldmann et al 2012)
