

Chemical Evolution

Evan Kirby

UC Irvine Center for Galaxy Evolution
(until Thursday)

Caltech
(starting Friday)

Schedule

- Monday, 11:30 am – 12:30 pm
 - *Sources of Nucleosynthesis and Timescales*
- Monday, 2:30 pm – 5:00 pm
 - Workshop with Carla Fröhlich
- Tuesday, 11:30 am – 12:30 pm
 - *Analytic Models of Chemical Evolution*
 - lots of equations
- Wednesday, 11:30 am – 12:30 pm
 - *Measurements in the Galaxy and Beyond*

Sources of Nucleosynthesis and Timescales

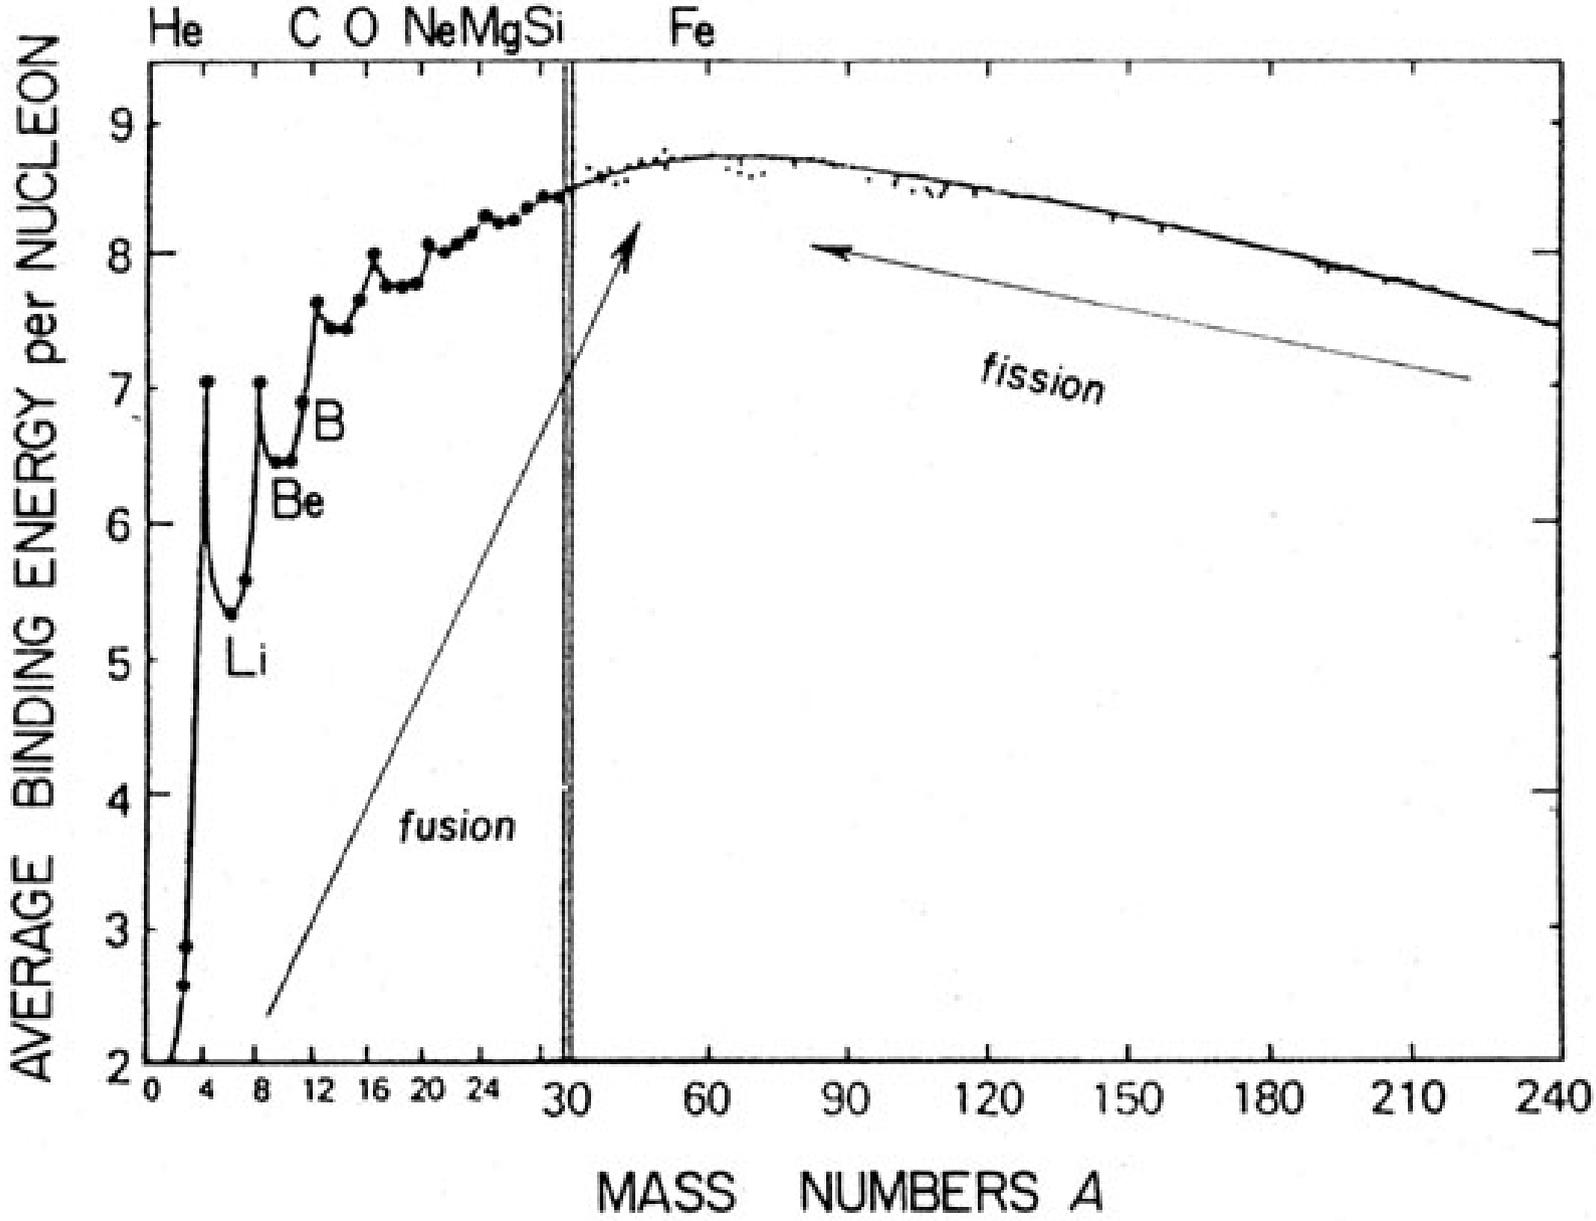

- Quick orientation to the elements
- Nucleosynthetic sources
 - Type II supernovae
 - Type Ia supernovae
 - AGB stars

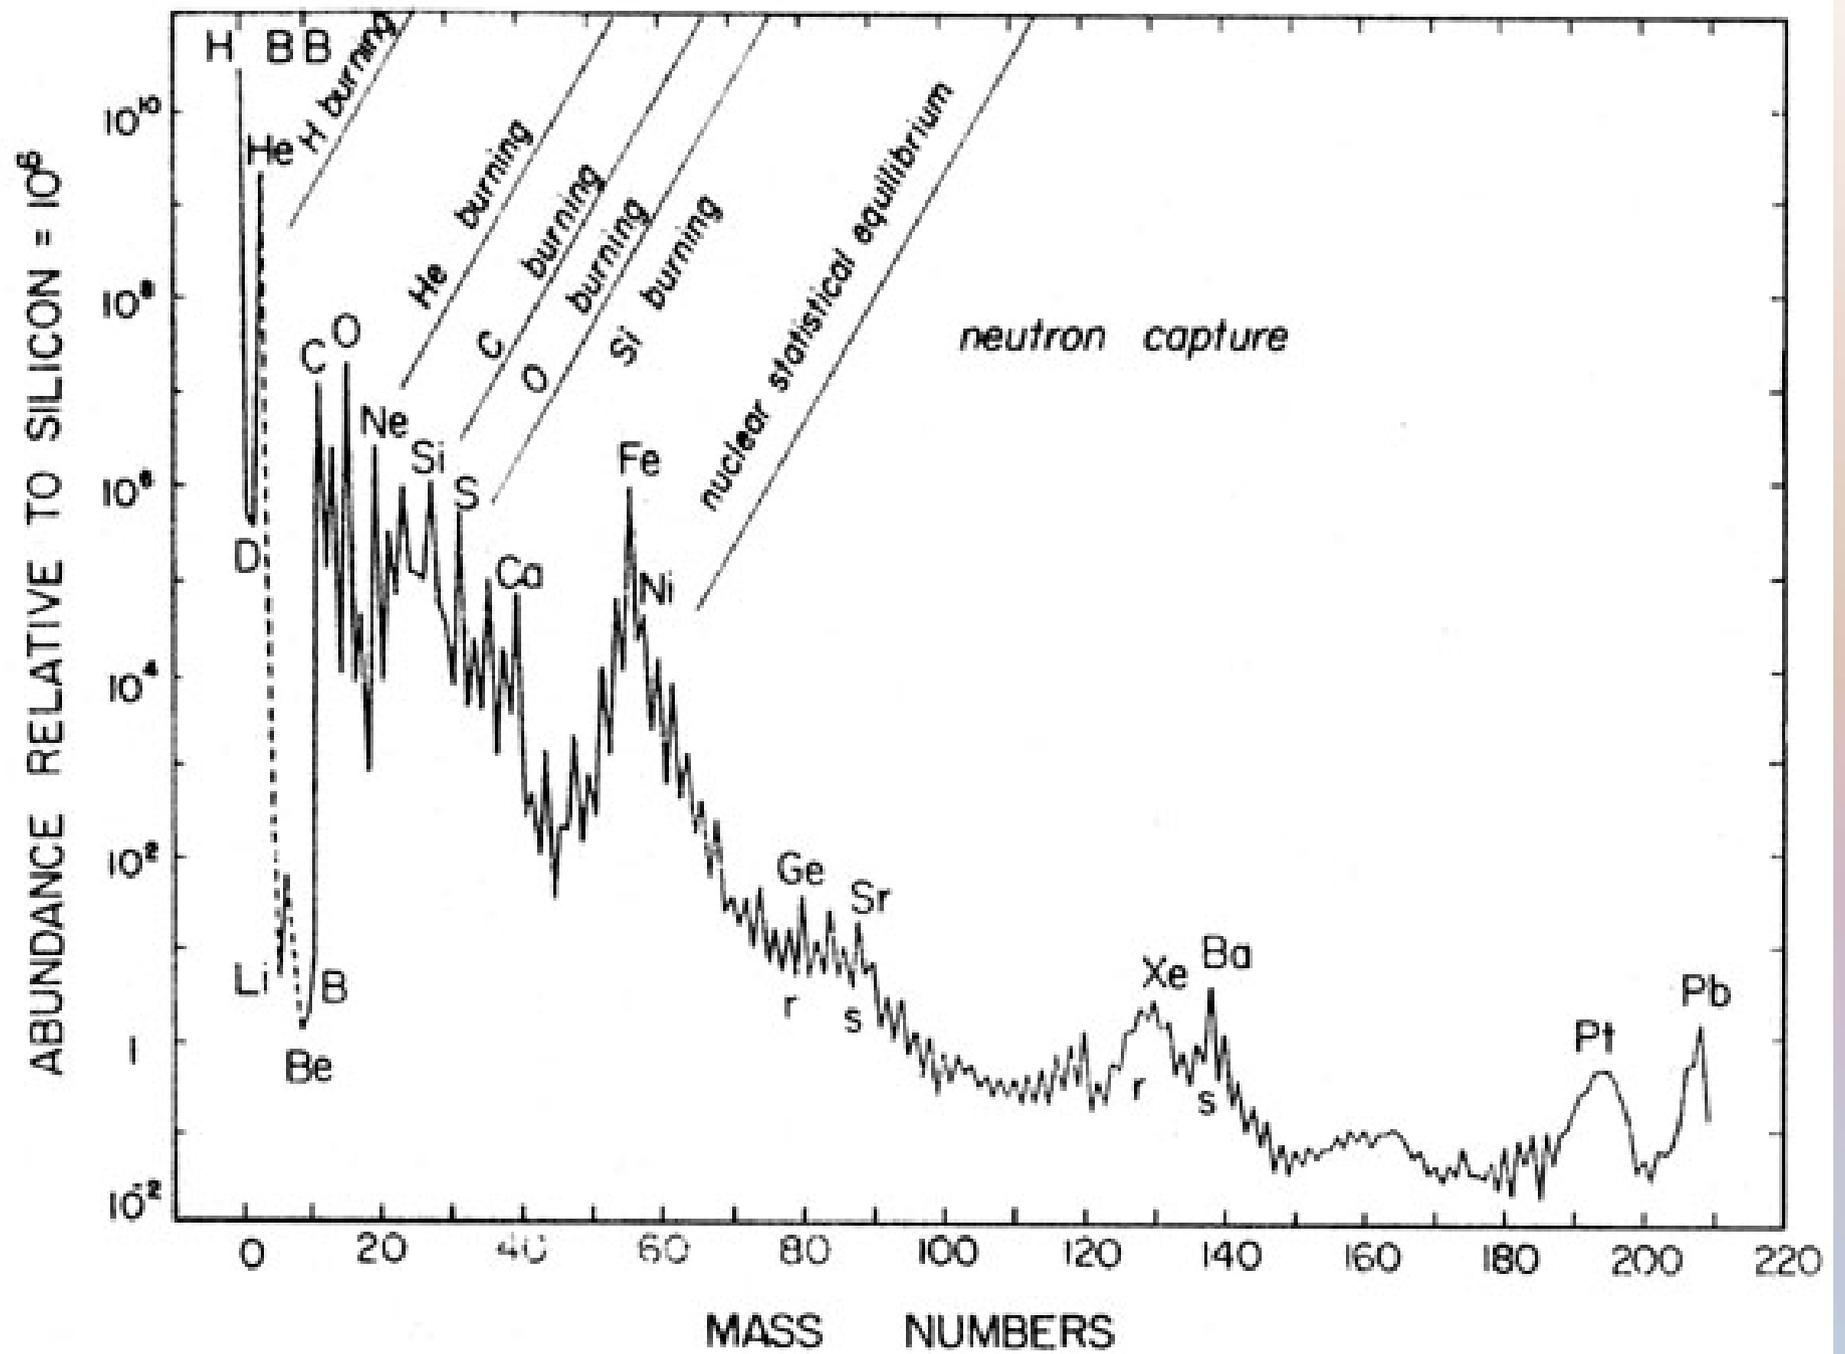

Periodic Table of the Elements

1 1IA 1A																	18 VIIIA 8A
1 H Hydrogen 1.0079	2 IIA 2A											13 IIIA 3A	14 IVA 4A	15 VA 5A	16 VIA 6A	17 VIIA 7A	2 He Helium 4.00260

Nucleosynthesis cheat sheet

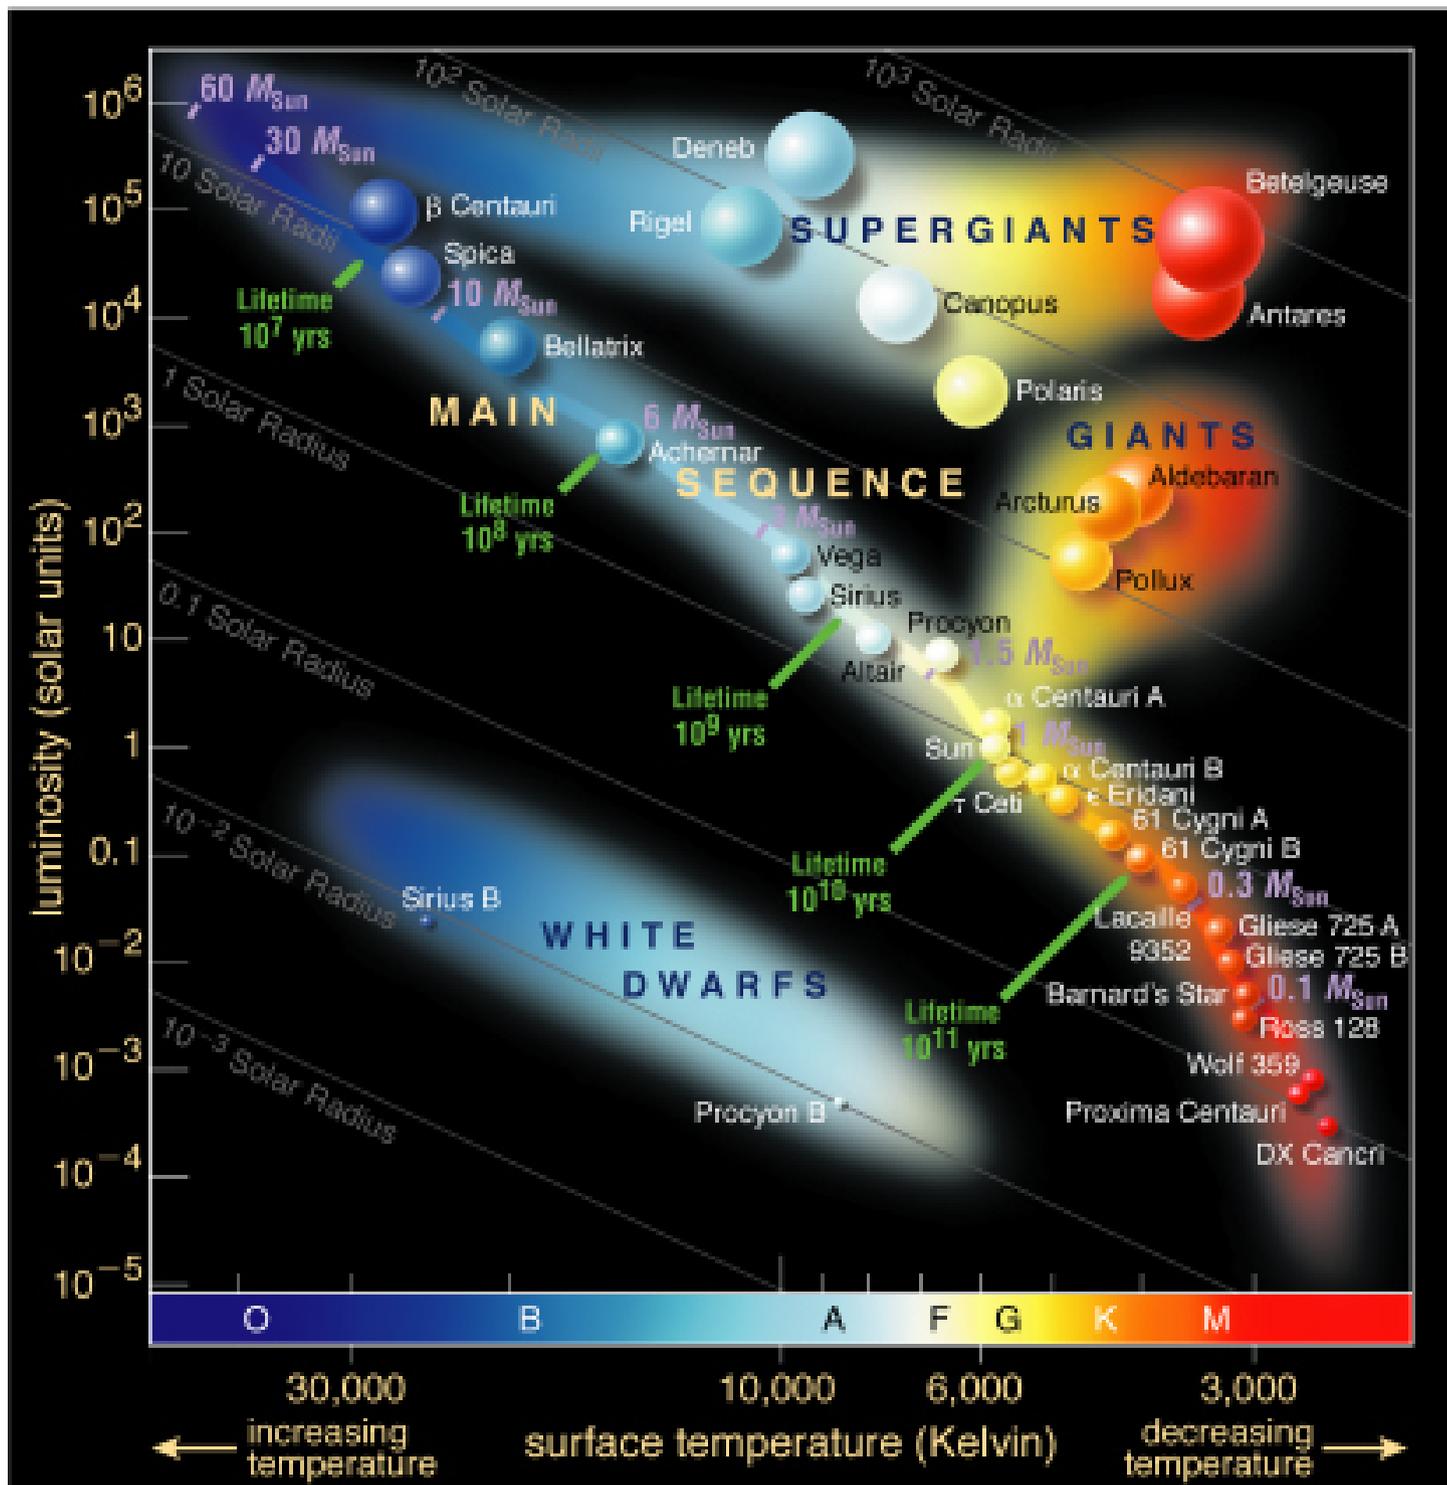

- Type II SNe: low-mass elements (He, C, N, O), α elements (O, Ne, Mg, Si, S, Ar, Ca), some Fe peak, *r*-process?
- Type Ia SNe: mostly Fe peak (Sc-Zn)
- AGB stars: He, C, N, *s*-process

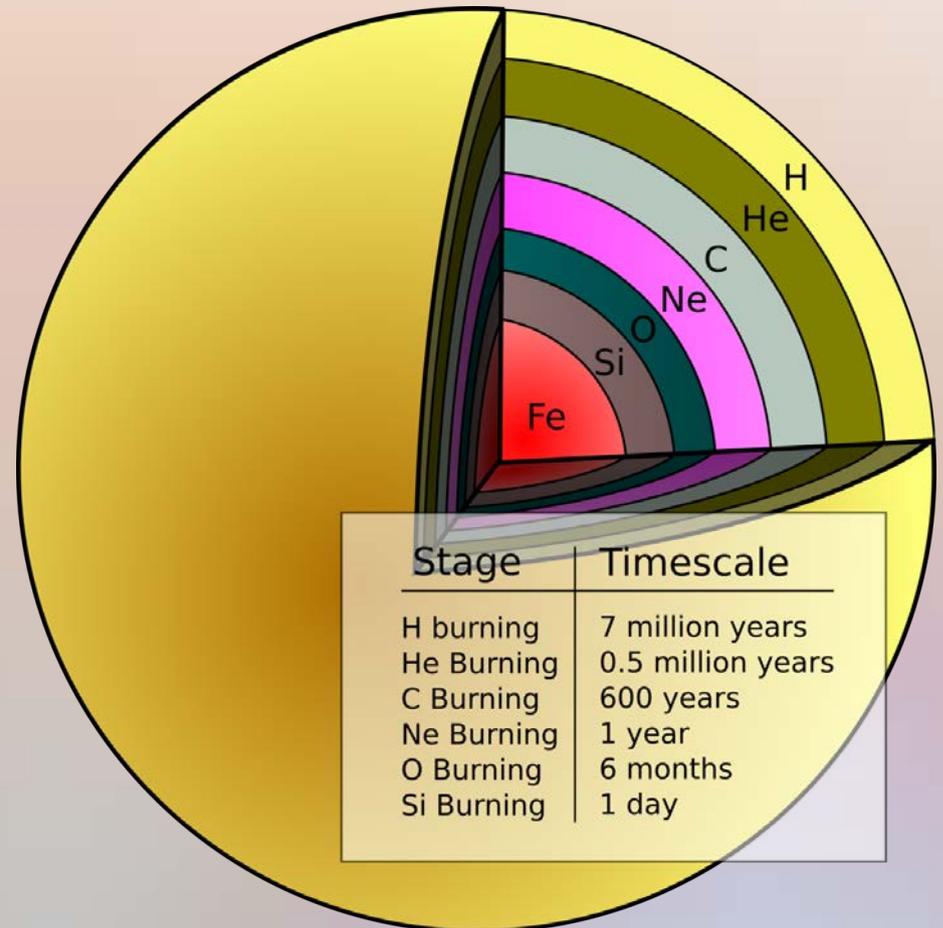

Nucleosynthetic sources

- Major
 - Core collapse (Type II) supernovae 4-25 Myr
 - Asymptotic giant branch (AGB) stars 50+ Myr
 - Thermonuclear (Type Ia) supernovae 0.1?-14 Gyr
- Minor
 - Winds from low-mass stars ≈ 1 Gyr
 - Neutron star mergers ≈ 1 Gyr
 - Cosmic ray spallation

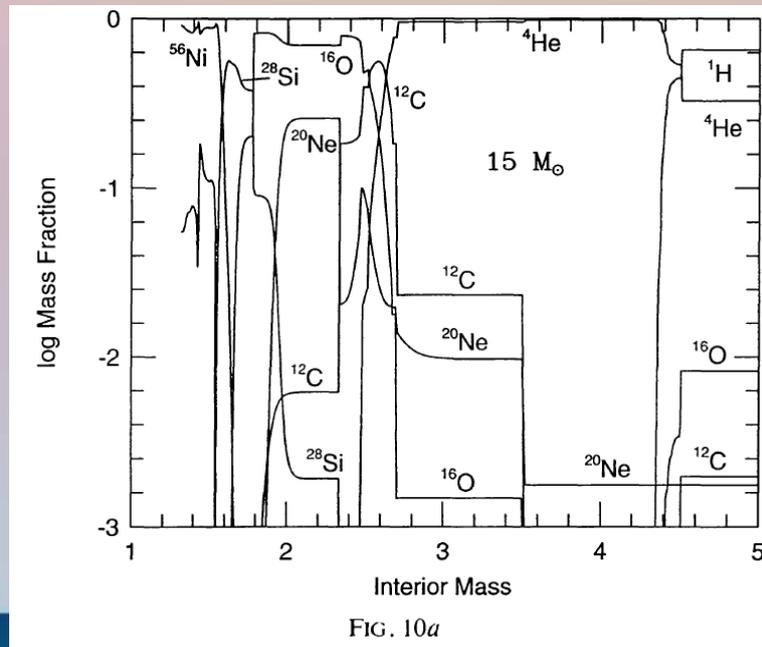

Core collapse (Type II) supernova

- 10-50 M_{\odot}
- 17% of stars by mass
- 0.8% by number

Core collapse nucleosynthesis (Woosley & Weaver 1995)

- pre-explosion
 - hydrostatic: He, C, N, O, Ne, Na, Mg, Al, (Si-Sc)
 - *s*-process
- explosion
 - neutrinos: F
 - explosive burning: (Si-Sc), Ti-Zn
 - *r*-process

Core collapse nucleosynthesis (Woosley & Weaver 1995)

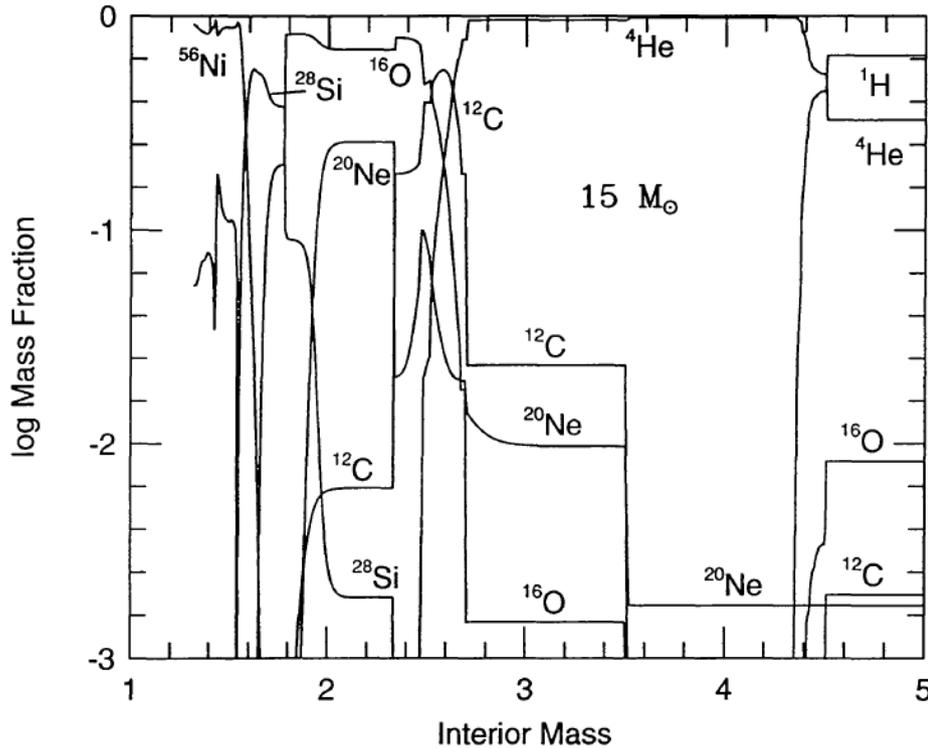

FIG. 10a

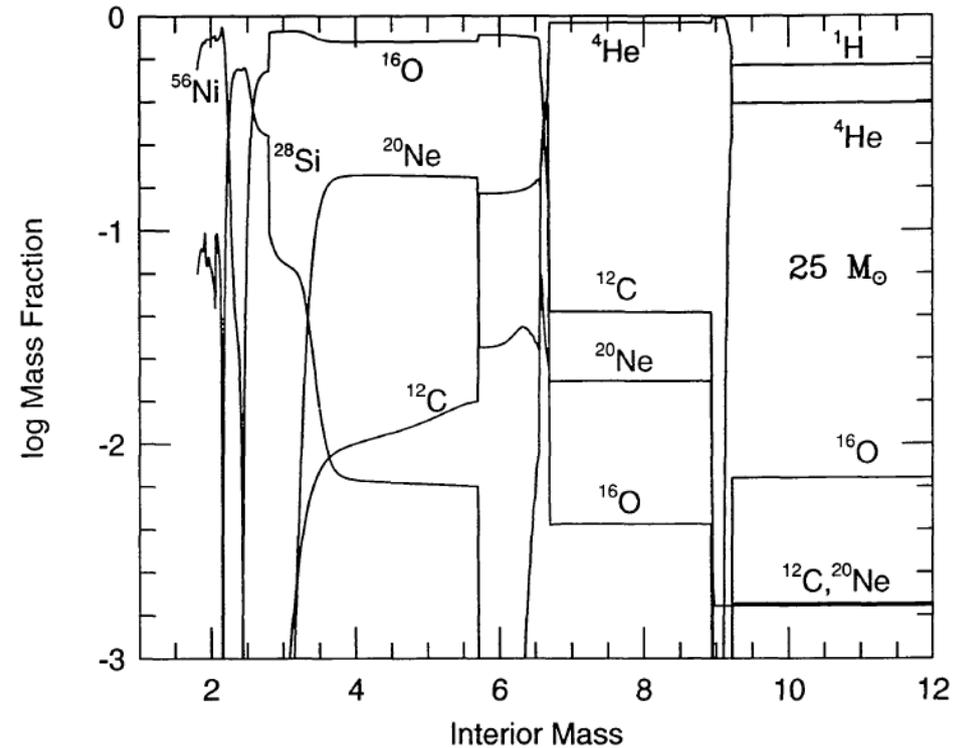

FIG. 10b

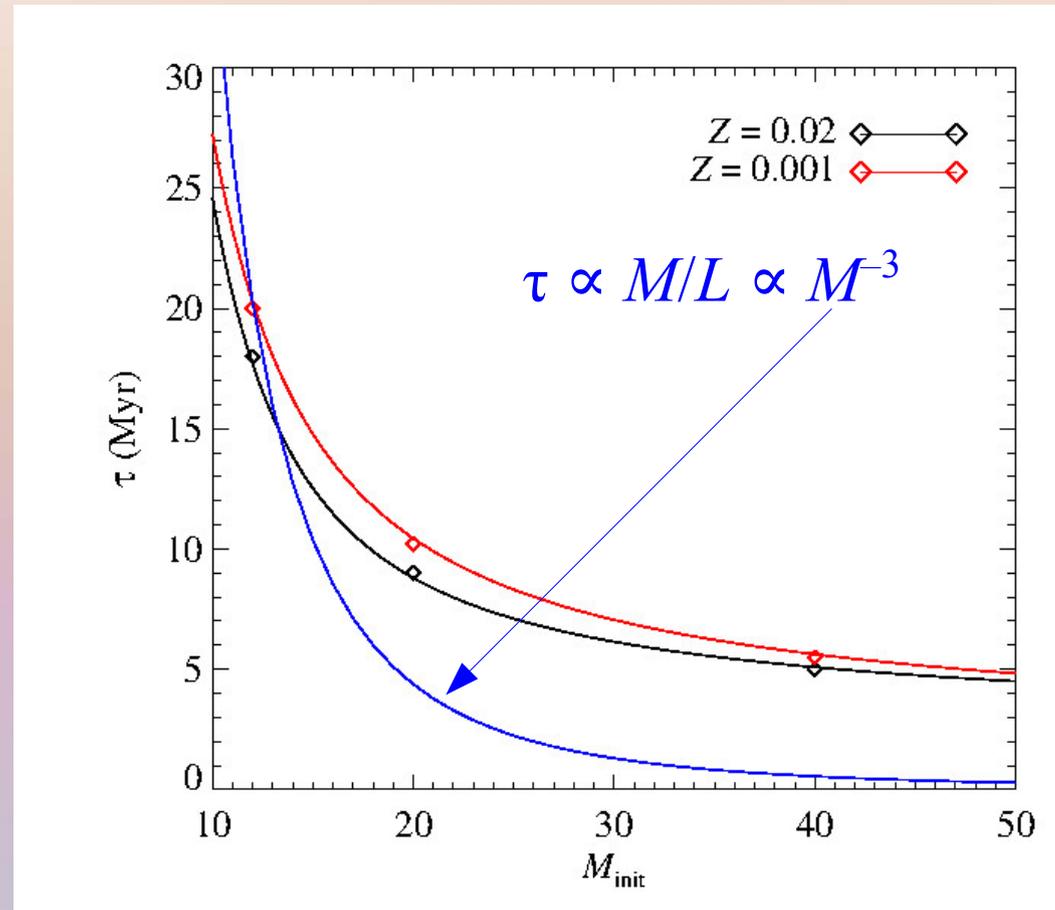

FIG. 10.—Final mass fractions of the major abundances — ^1H , ^4He , ^{12}C , ^{16}O , ^{20}Ne , ^{28}Si , and ^{56}Ni —(a) the inner $5 M_{\odot}$ of a $15 M_{\odot}$ solar metallicity supernova (model S15A); (b) the inner $12 M_{\odot}$ of the ejecta of a $25 M_{\odot}$ solar metallicity supernova (model S25A). Each had an explosion energy of 1.2×10^{51} ergs (Table 3).

Type II delay time distribution

$$Z = 0.02: \quad \tau = (9.5 \times 10^9) M_{\text{init}}^{-2.8} + (3.6 \times 10^7) M_{\text{init}}^{-0.65} + 1.5 \times 10^6$$

$$Z = 0.001: \quad \tau = (6.5 \times 10^9) M_{\text{init}}^{-2.7} + (1.0 \times 10^8) M_{\text{init}}^{-0.90} + 1.7 \times 10^6$$

$$dN \propto M_{\text{init}}^{-2.35} dM \quad (\text{Salpeter IMF})$$

Type Ia nucleosynthesis

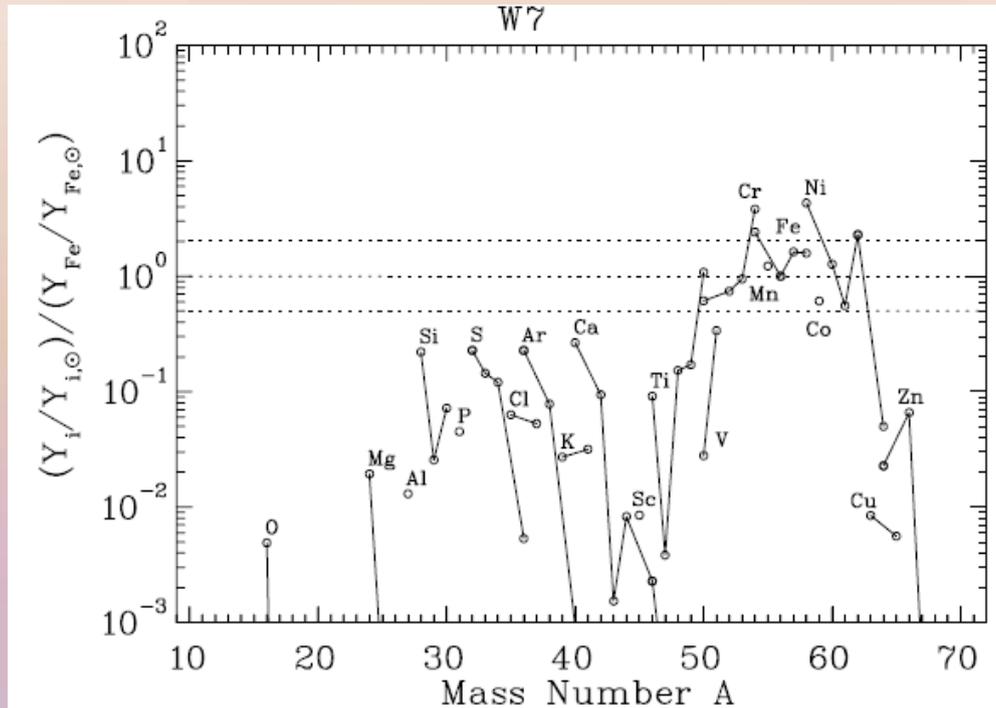

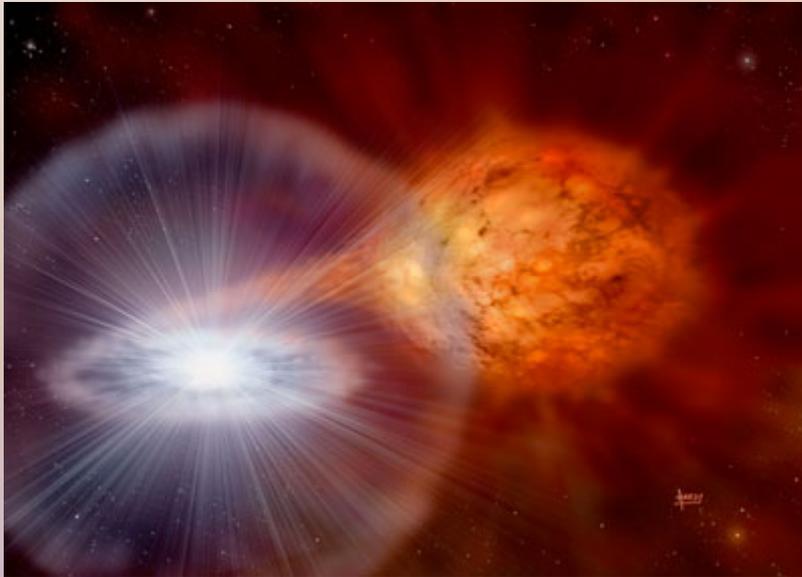

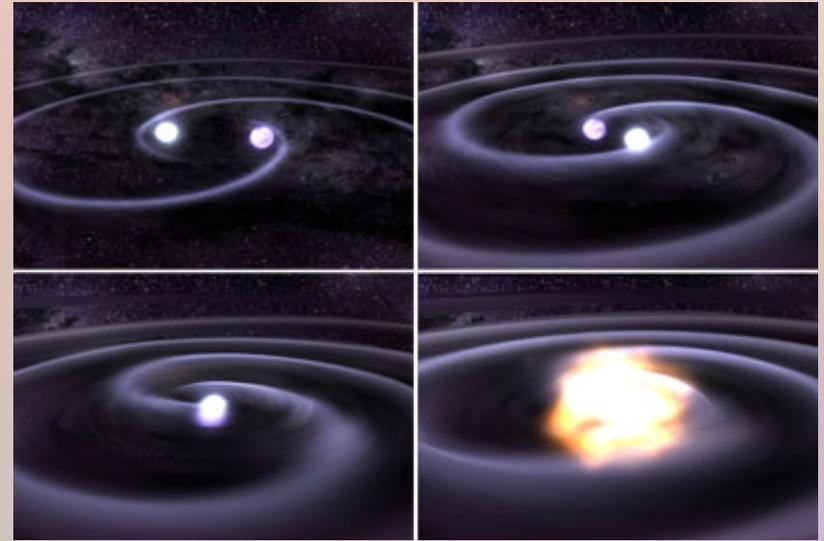

FIG. 12.—Ratio of abundances to solar predicted in model W7 (this is a recalculation of the 1986 model [Thielemann et al. 1986] with presently available updated reaction rates and a screened NSE treatment for temperatures beyond 6×10^9 K, as described in Hix & Thielemann 1996). Isotopes of one element are connected by lines. The ordinate is normalized to ^{56}Fe . Intermediate mass elements exist but are underproduced by a factor of 2–3 in comparison to Fe-group elements. Among the Fe-group, ^{54}Cr and ^{58}Ni are overproduced by a factor of 4, which exceeds the permitted factor of ~ 3 .

Iwamoto et al. 1999, ApJS, 125, 439 (500+ citations)

Type Ia models: SD vs. DD

single degenerate

double degenerate

Type Ia DTD

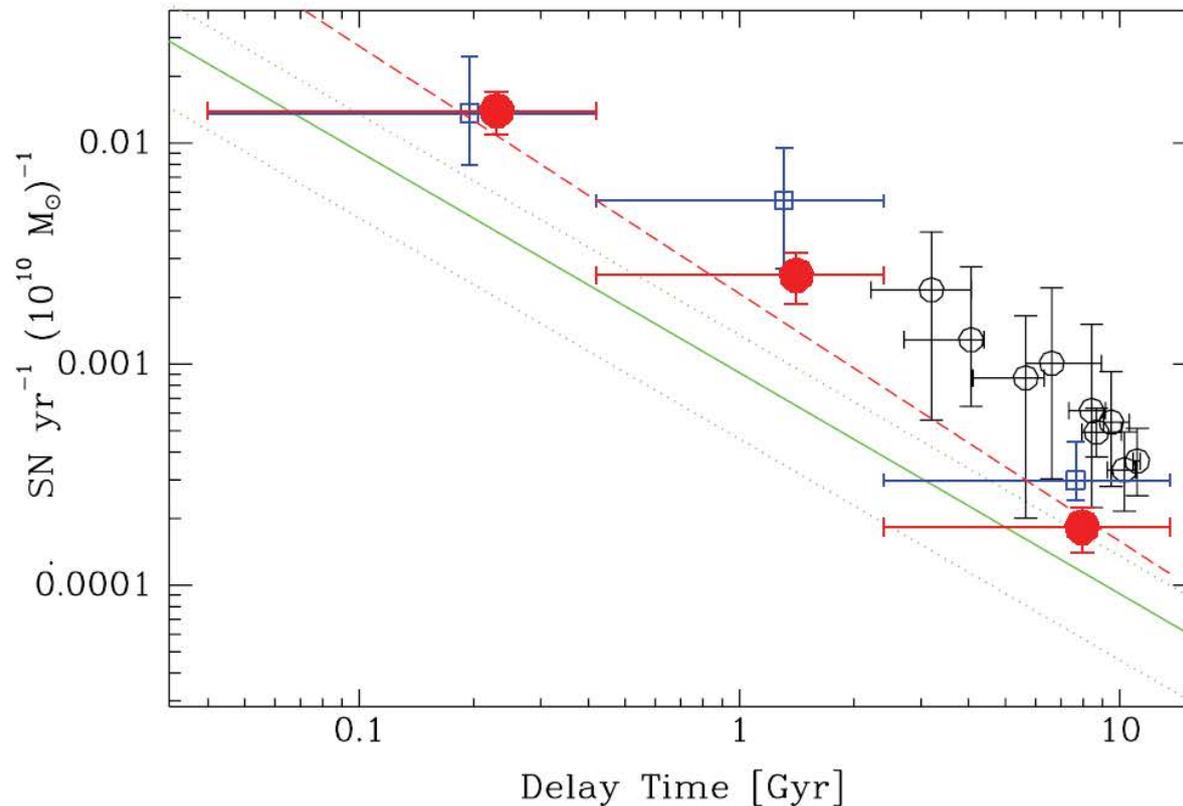

Figure 1. Recovered SN Ia DTD for the SDSS2 SN sample. Filled red circles mark the best-fitting DTD values for each time bin, whose time range is indicated by the horizontal error bars. Vertical error bars show the Gaussian 1σ uncertainties. Red dashed line is the best power-law fit, with index -1.12 , to the recovered DTD. Previous DTD measurements also shown are as follows: M11 analysis of the nearby LOSS sample (empty blue squares, with central values slightly shifted to the left, for clarity); Maoz et al. (2010) analysis based on SN Ia rates in galaxy clusters (empty black circles); and t^{-1} power-law DTD found by Graur et al. (2011), based on comparison of volumetric SN Ia rates and cosmic SFH (solid green line, with dotted lines marking the 1σ range).

Maoz, Mannucci, & Brandt 2012, MNRAS, 426, 3282

Type Ia delay time distribution

$$\Psi_{\text{Ia}} \approx 10^{-3} \tau^{-1.1} \text{ SN Gyr}^{-1} M_{\odot}^{-1} \quad \tau \gtrsim 0.11 \text{ Gyr}$$

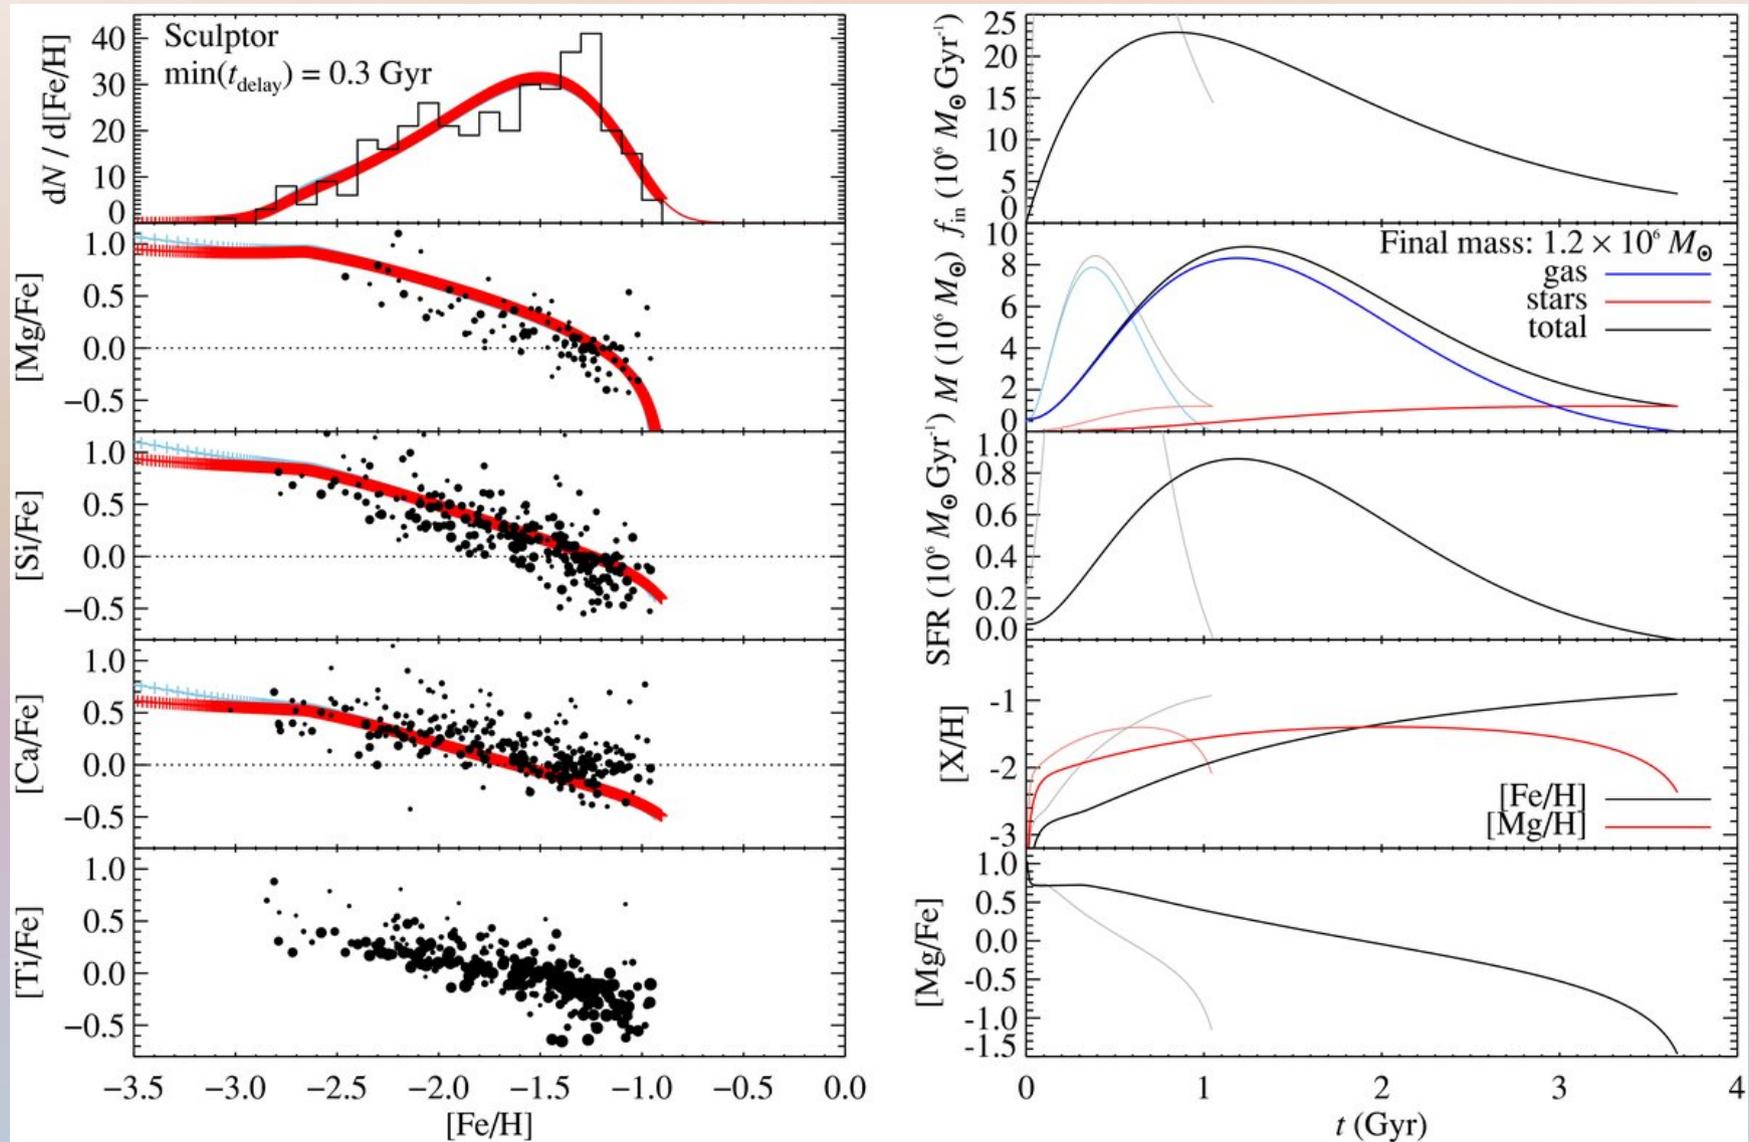

$$\Psi_{\text{Ia}} = ??? \quad \tau < 0.11 \text{ Gyr}$$

$$\int_{0.11 \text{ Gyr}}^{13.6 \text{ Gyr}} \Psi_{\text{Ia}} d\tau = 4.8 \times 10^{-3} \text{ SN } M_{\odot}^{-1}$$

$$\int_{0.11 \text{ Gyr}}^{\infty} \Psi_{\text{Ia}} d\tau = 1.2 \times 10^{-2} \text{ SN } M_{\odot}^{-1}$$

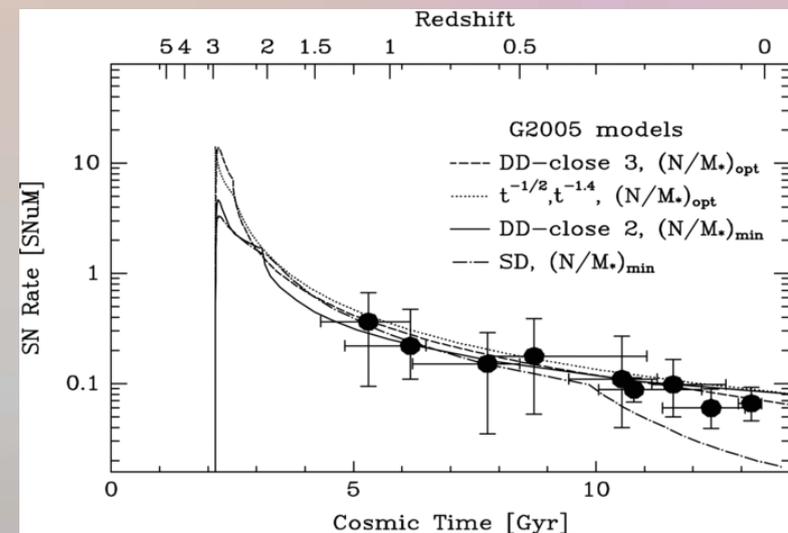

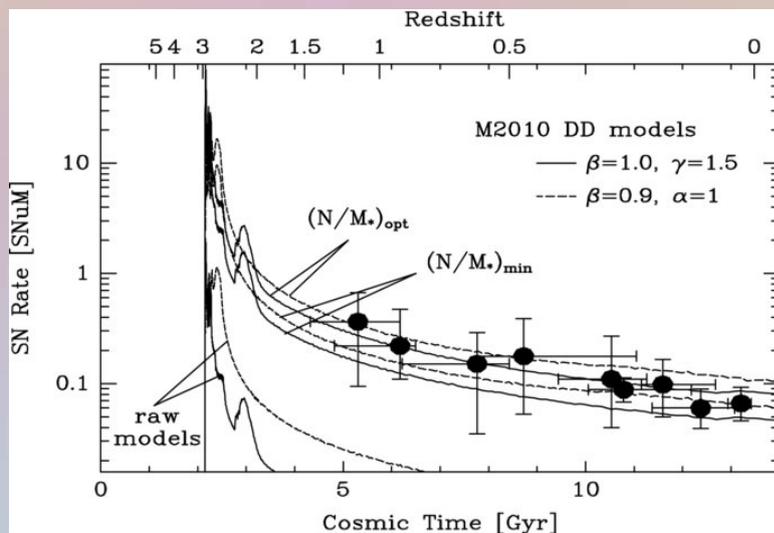

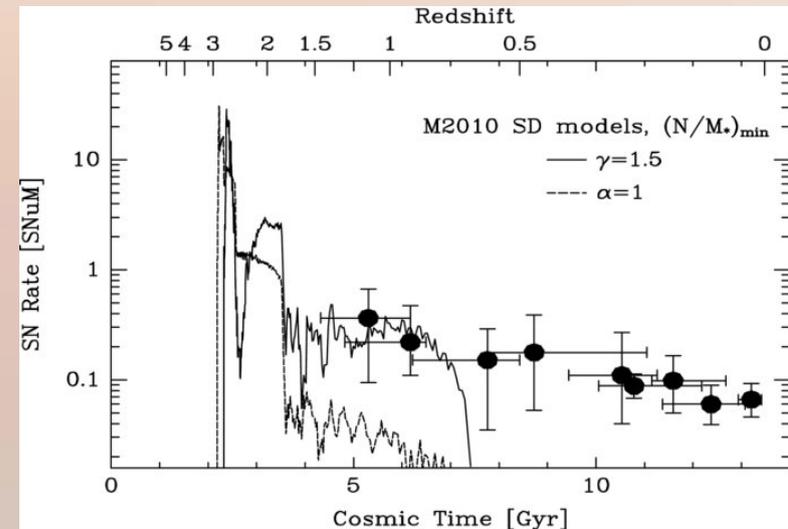

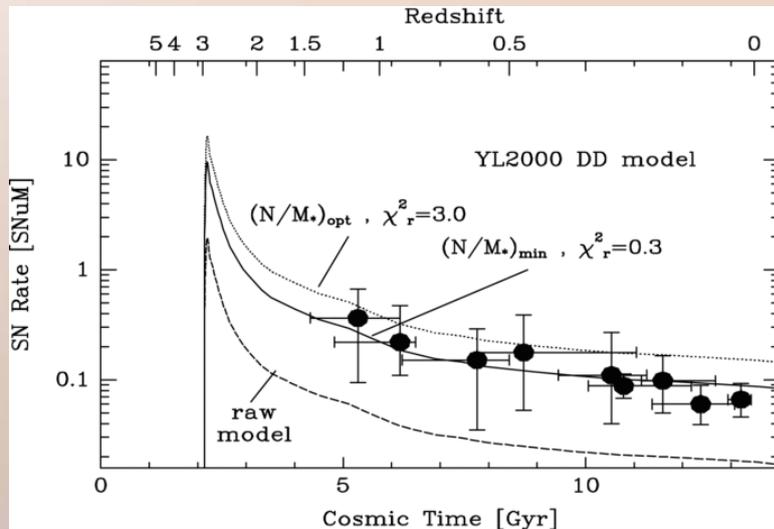

$$\int_{0.01 \text{ Gyr}}^{13.6 \text{ Gyr}} \Psi_{\text{Ia}} d\tau = 8.1 \times 10^{-3} \text{ SN } M_{\odot}^{-1}$$

Chart of the Nuclides

Created at National Superconducting Cyclotron Laboratory, Michigan State University, 2013 using LISE-4+

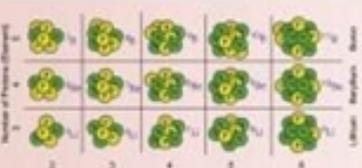

Operation of NSCL is a national user facility supported by the Department of Nuclear Physics Program of the U.S. National Science Foundation.

Why a Chart?

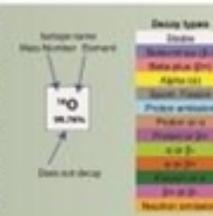

Nuclei contain even smaller particles: protons and neutrons. The number of protons in a nucleus determines what element it is. For example, four protons (yellow circles with a '+' sign) make a helium (^4He) nucleus. The periodic table organizes the known elements by "atomic number" (the number of protons).

The number of neutrons in a nucleus determines what isotope it is. For example, the number of neutrons in a nucleus determines what element it is. For example, four protons (yellow circles with a '+' sign) make a helium (^4He) nucleus. The periodic table organizes the known elements by "atomic number" (the number of protons).

Read the Chart of Nuclides

Isotope Name	Mass Number	Element
Deuterium	2	Hydrogen
Helium-3	3	Helium
Helium-4	4	Helium
Lithium-6	6	Lithium
Lithium-7	7	Lithium
Boron-10	10	Boron
Boron-11	11	Boron
Carbon-12	12	Carbon
Carbon-13	13	Carbon
Carbon-14	14	Carbon
Nitrogen-14	14	Nitrogen
Nitrogen-15	15	Nitrogen
Oxygen-16	16	Oxygen
Oxygen-17	17	Oxygen
Oxygen-18	18	Oxygen
Fluorine-19	19	Fluorine
Neon-20	20	Neon
Neon-21	21	Neon
Neon-22	22	Neon

Half-life scale: 10¹⁰ years, 10⁹ years, 10⁸ years, 10⁷ years, 10⁶ years, 10⁵ years, 10⁴ years, 10³ years, 10² years, 10¹ years, 10⁰ years, 10⁻¹ years, 10⁻² years, 10⁻³ years, 10⁻⁴ years, 10⁻⁵ years, 10⁻⁶ years, 10⁻⁷ years, 10⁻⁸ years, 10⁻⁹ years, 10⁻¹⁰ years.

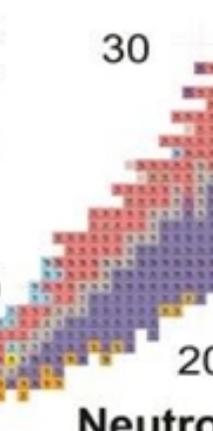

Common types of Radioactive Decay

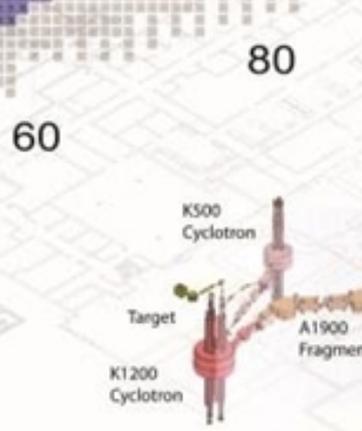

Alpha decay: A nucleus emits an alpha particle (two protons and two neutrons).
Beta minus decay: A neutron transforms into a proton, emitting an electron and an antineutrino.
Beta plus decay: A proton transforms into a neutron, emitting a positron and a neutrino.

Protons (Z)

Neutrons (N)

Acceleration: To study rare isotopes, we must first create them. Ion sources feed partially ionized atoms of a stable, common isotope to the K500 or direct ion source at K1200, which accelerates the ions to 10,000 kilovolts (around a 70 percent of the speed of light). The larger and more powerful K500 cyclotron boosts the ions to nearly half the speed of light.

Production: The beam of ions then collides with a thin target, creating a wide variety of new, possibly ion and radioactive isotopes. These resulting isotopes are filtered with the A1900 fragment separator, which carefully selects particular ions isotopes from the full beam of nuclear reaction products.

Exploration: NSCL detectors measure properties of nuclei. The strength of the three-ring 5800 Spectrograph, located at one end of the beamline. This device can "snare" ions to detect particles released after one isotope nuclei smash into a target, measuring the structure of the nucleus. Other detectors analyze patterns of emitted neutrons, or weigh isotopes with beam-based balances.

The Future: The cyclotrons will be replaced with a linear accelerator as NSCL transitions into the Facility for Rare Isotope Beams (FRIB). The Department of Energy funded laboratory will lead the world in rare isotope research, producing hundreds of times more nuclei at the same energy as what at NSCL. FRIB will produce new frontiers in nuclear science with a higher production rate by 2025.

What is NSCL?
 • National Superconducting Cyclotron Laboratory (NSCL) is a world-class nuclear research laboratory that produces rare isotopes for "experimentation" using nuclear beams at a high speed of light. Scientists can use beams to gather evidence of nuclear properties, studying them in order to better understand our universe and find the origins of elements in the multiple star bodies.

Studying Nuclei
 The vast majority of isotopes on the Chart are radioactive and they are typically not found on Earth. New isotopes allow us to study about nuclear properties:
 • Are isotopes on the edge of nuclear existence?
 • Do they occur naturally on Earth?
 • How do half-lives of new isotopes compare to a traditional isotope?
 • Produce significant amounts of radiation with their rapid decay.

Making Rare Isotopes
 The cyclotrons will be replaced with a linear accelerator as NSCL transitions into the Facility for Rare Isotope Beams (FRIB). The Department of Energy funded laboratory will lead the world in rare isotope research, producing hundreds of times more nuclei at the same energy as what at NSCL. FRIB will produce new frontiers in nuclear science with a higher production rate by 2025.
