

Sunrise:

Panchromatic SED Models of Simulated Galaxies

Lecture 2:

Working with
Sunrise

Patrik Jonsson

Harvard-Smithsonian Center for Astrophysics

Patrik Jonsson – HIPACC Summer School 2010

Lecture outline

- Lecture 1: Why Sunrise? What does it do? Example science. How to use the outputs? Projects?
- Lecture 2: Sunrise work flow. Parameters, convergence, other subtleties.
- Lecture 3: Radiation transfer theory. Monte Carlo. Polychromatic MC.
- Lecture 4: Dust emission, dust self-absorption. Sunrise on GPUs.

Working with Sunrise

Episode 1: Building

Patrik Jonsson – HIPACC Summer School 2010

A long process...

- This is explained in detail on “Compiling” page on the Sunrise Wiki:
- Sunrise is written in C++, with several dependencies
 - Blitz++ (matrix library)
 - CCfits (C++ I/O library)
 - cfitsio (C I/O library)
 - Boost (generally useful C++ stuff)
 - HDF5 (optional)
 - CUDA (if you have a GPU)
- Works with gcc or Intel icpc

A long process...

- Won't go through the whole thing, but:
- Unless you are very experienced in compiling C++ programs, expect to have to fiddle a bit. Every system's a bit different.
- If you really can't figure it out, post to the Sunrise discussion group.

Working with Sunrise

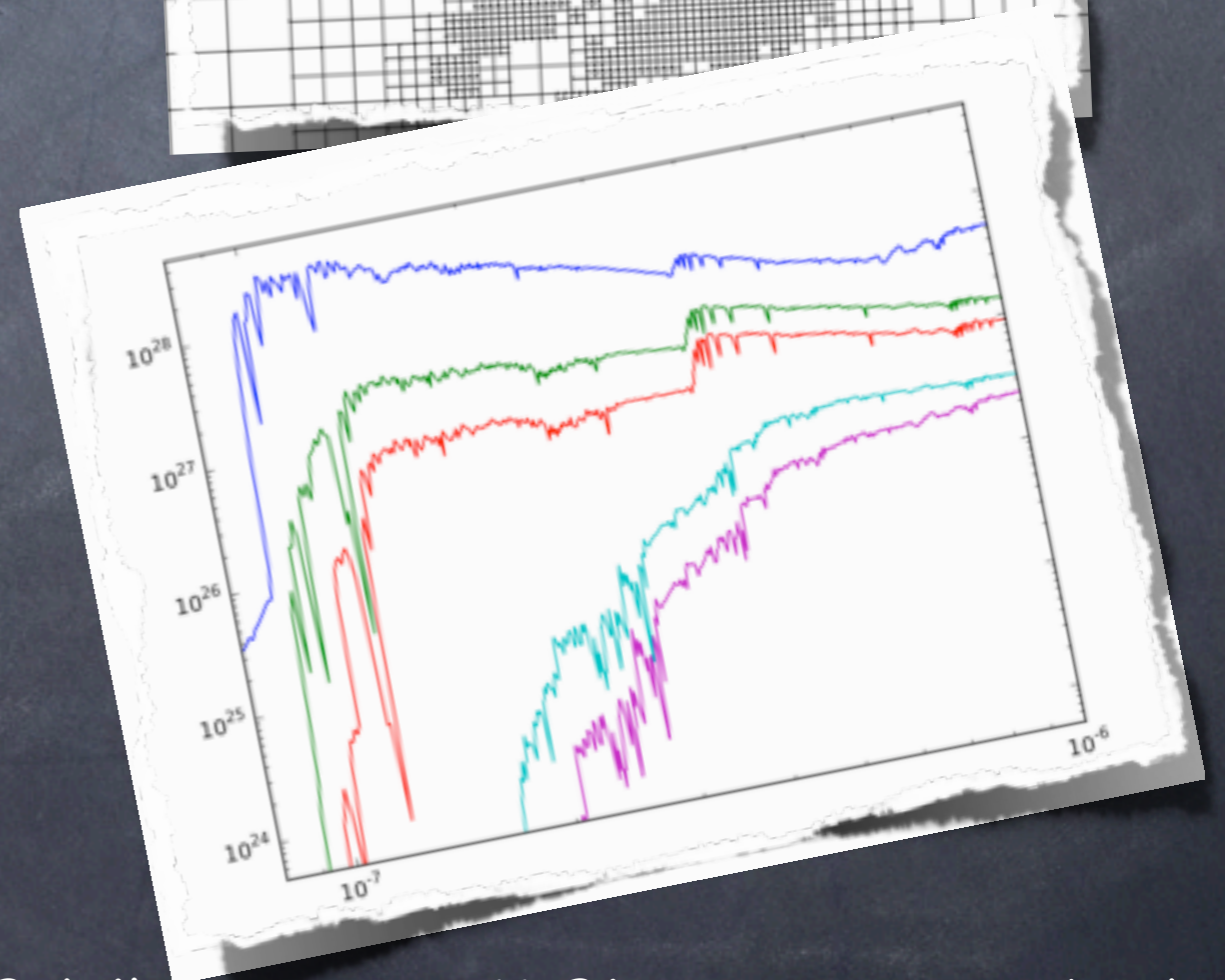

Episode 2: Workflow

Workflow

- This is explained in detail on “Sunrise Overview” page on the Sunrise Wiki
- Processing a hydro snapshot with Sunrise involves running 3 executables
 - **sfrhist** – calculation of source SEDs and adaptive-mesh grid
 - **mcrx** – the actual radiation transfer calculation
 - **broadband** – integration of outputs over filter bands to get magnitudes and images

First: sfrhist

- Loads the snapshot data
- Constructs the adaptive mesh grid for the dust distribution
- Calculates the SEDs of the stellar particles, based on age and metallicity
- Calculates AGN SED (if applicable)

Second: mcrx

- Does the Monte Carlo radiation transfer (we'll talk about this tomorrow)
- Proceeds in several stages:
 - without dust
 - with dust
 - dust temperature
 - dust emission
- We looked at the output files yesterday

Third: broadband

- Creates images and magnitudes in specific filter bands
- Can do redshift effects:
 - k-correction
 - surface-brightness dimming

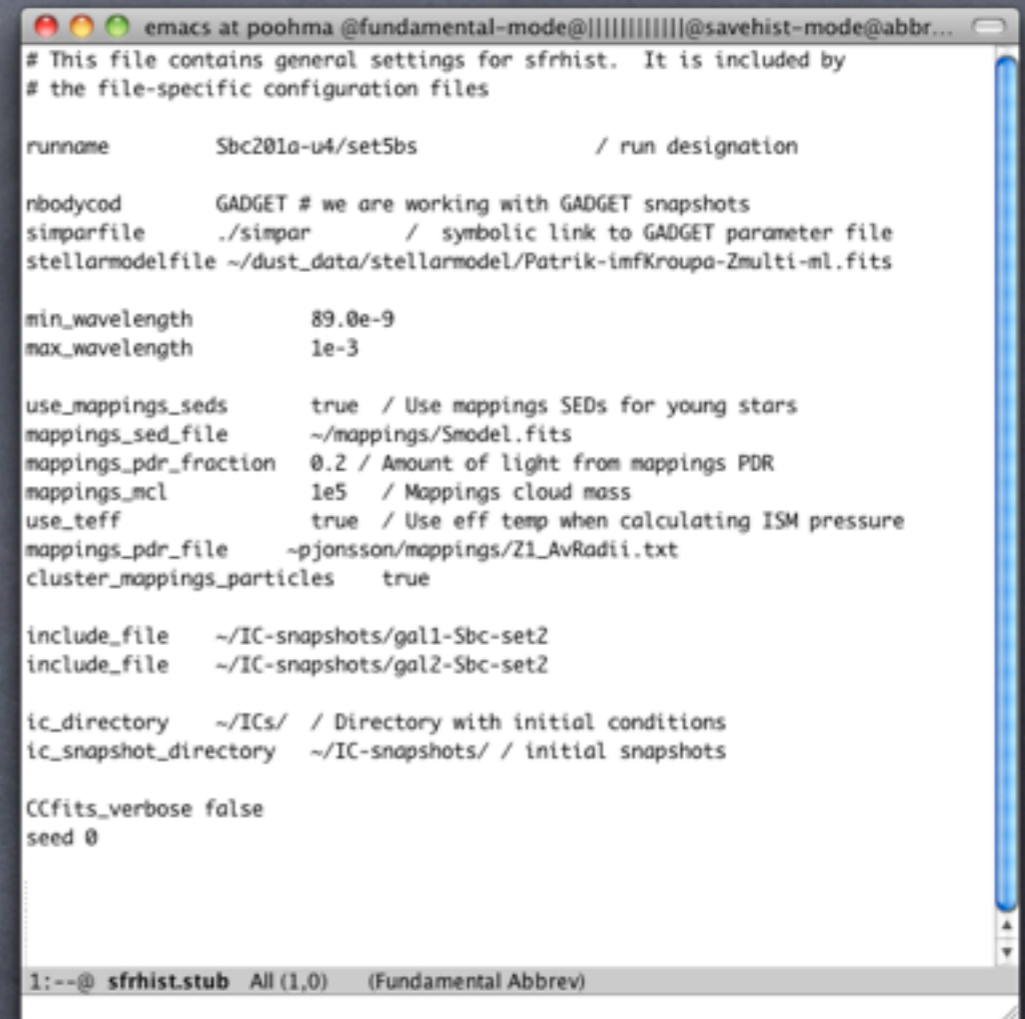

Working with Sunrise

Episode 3: Configuration

Configuration files

- Each of the executables take a configuration file as the argument
- keyword-value pairs

```
emacs at poohma @fundamental-mode@...@savehist-mode@abbr...
# This file contains general settings for sfrhist. It is included by
# the file-specific configuration files

runname      Sbc201a-u4/set5bs          / run designation

nbodycod     GADGET # we are working with GADGET snapshots
simparfile   ./simpar          / symbolic link to GADGET parameter file
stellarmodelfile ~/dust_data/stellarmodel/Patrik-imfKroupa-Zmulti-ml.fits

min_wavelength  89.0e-9
max_wavelength  1e-3

use_mappings_seds true / Use mappings SEDs for young stars
mappings_sed_file ~/mappings/Smodel.fits
mappings_pdr_fraction 0.2 / Amount of light from mappings PDR
mappings_mcl 1e5 / Mappings cloud mass
use_teff true / Use eff temp when calculating ISM pressure
mappings_pdr_file ~pjonsson/mappings/Z1_AvRadii.txt
cluster_mappings_particles true

include_file ~/IC-snapshots/gal1-Sbc-set2
include_file ~/IC-snapshots/gal2-Sbc-set2

ic_directory ~/ICs/ / Directory with initial conditions
ic_snapshot_directory ~/IC-snapshots/ / initial snapshots

CCfits_verbose false
seed 0

1:--@ sfrhist.stub All (1,0) (Fundamental Abbrev)
```

sfrhist configuration

- The sfrhist options are explained in detail in “Sfrhist Config and Output Format” on the Wiki.
- sfrhist configuration comprises 4 main sets:
 - stellar population model (e.g. Starburst99)
 - MAPPINGS parameters
 - grid creation parameters
 - galaxy initial conditions (if simulation starts with galaxies)

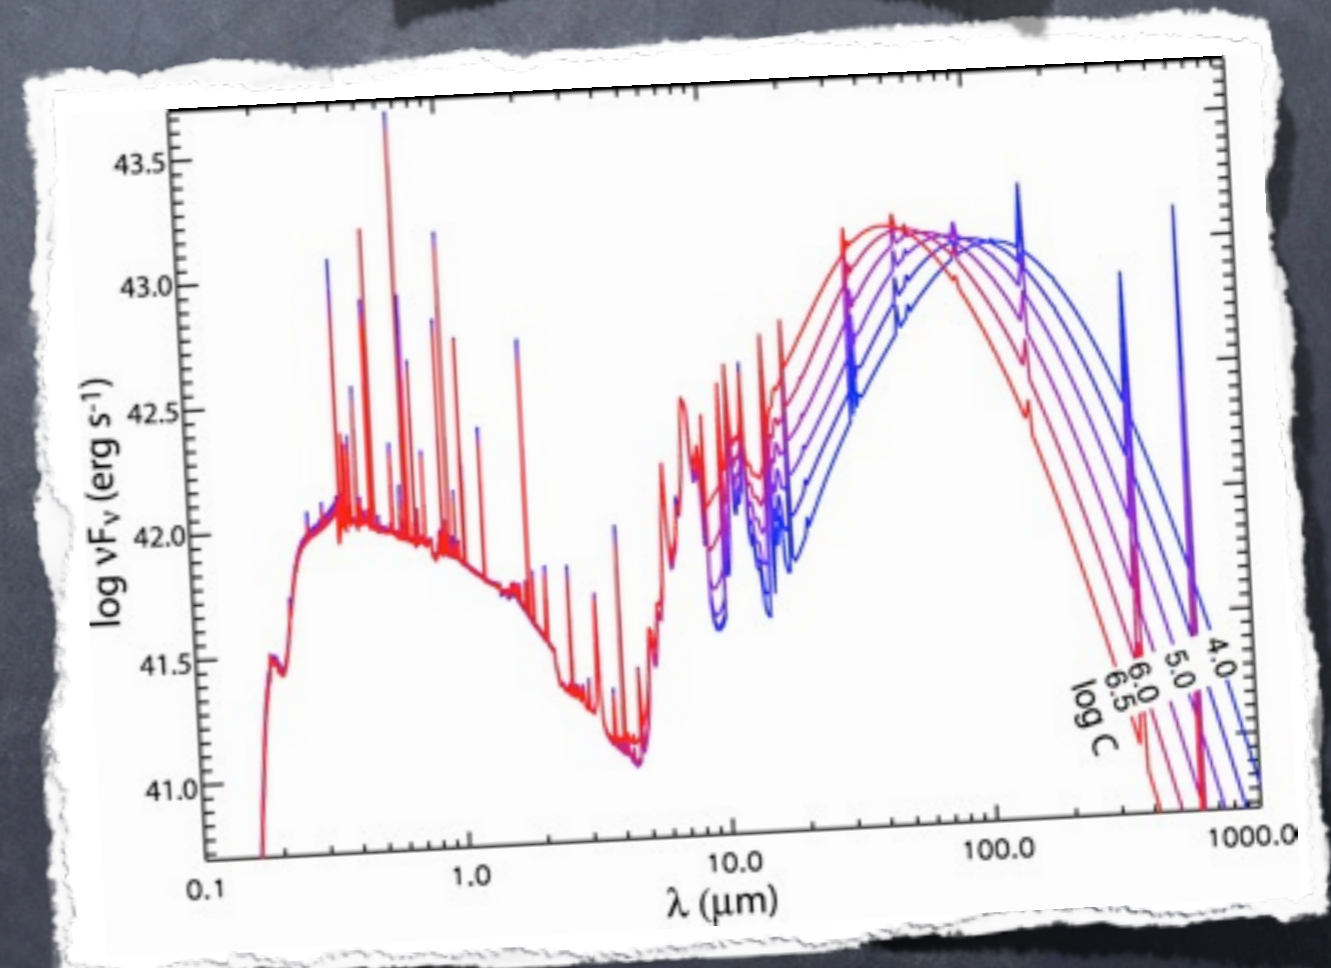

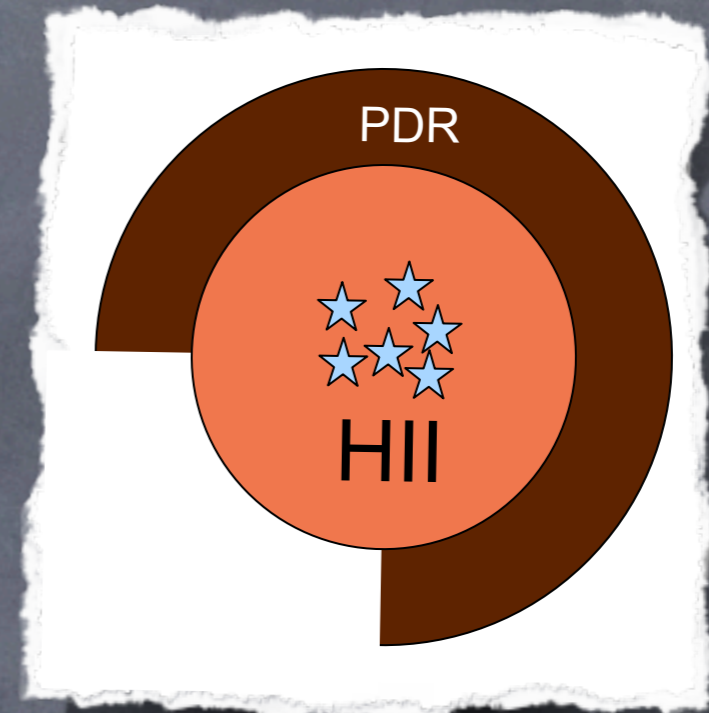

MAPPINGS models

- Star-forming regions are a problem:
 - Young stars are enshrouded in dust
 - HII regions and molecular clouds are (normally) not resolved
 - Want to predict line strengths
- Solution: Use a separate "sub-particle" model of HII regions/MCs

MAPPINGS models

- MAPPINGS models are parametrized by:
 - Z (from hydro)
 - ISM pressure (from sim)
 - PDR covering frac
 - Cluster mass
- 2 config parameters
- Each particle $<10\text{Myr}$ old gets its own model
- Groves et al. (2008)

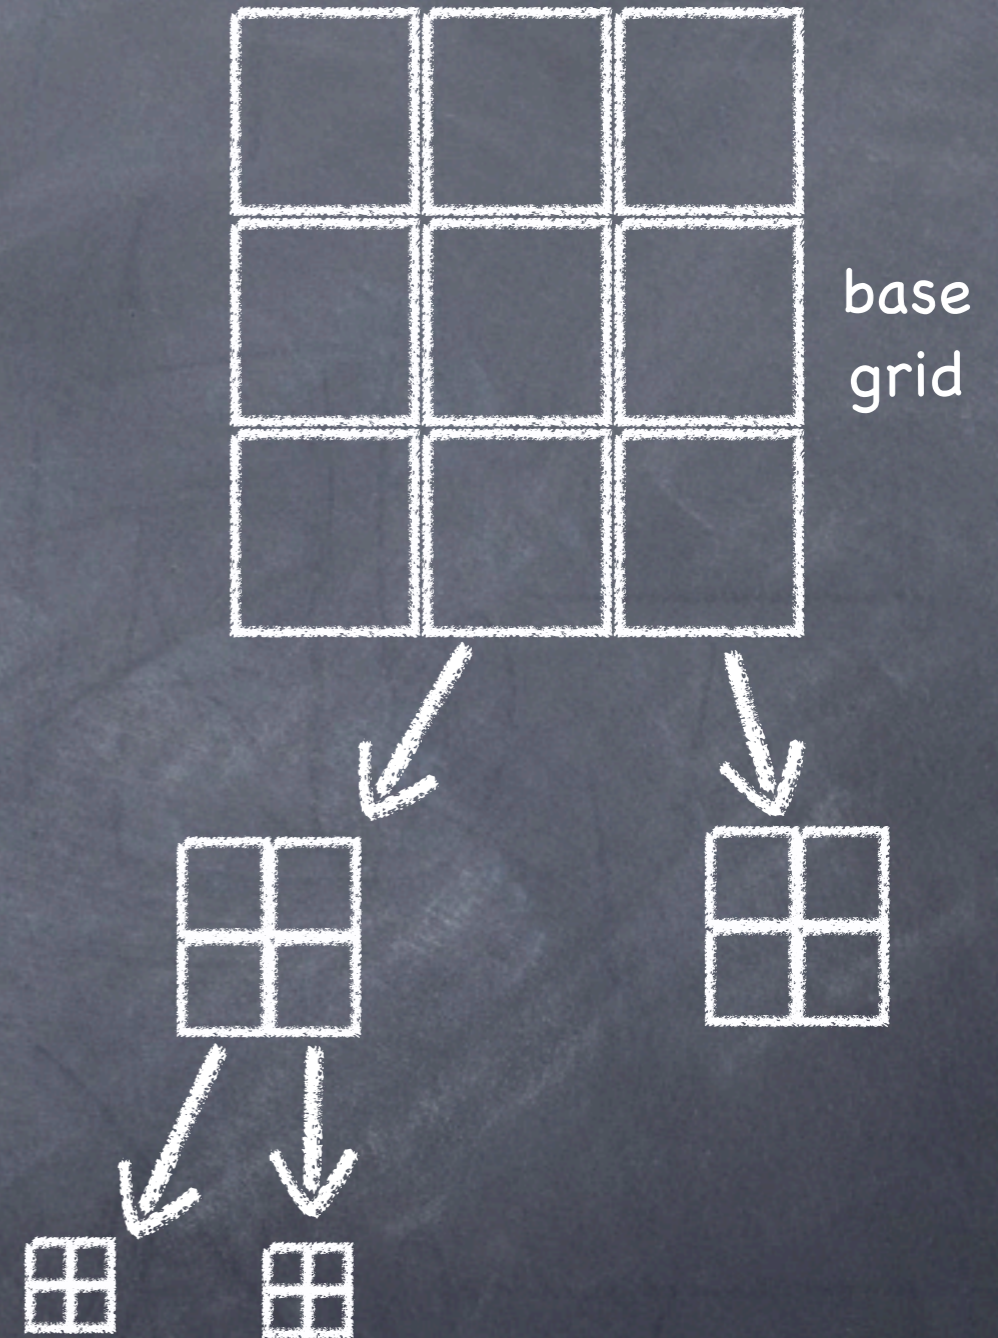

Grid creation parameters

- Sunrise uses a recursively refined grid structure ("octree")
- Algorithm described in Sunrise papers
- There is NO local way to determine refinement – depends on unknown radiation field
- Parameters explained on Wiki: <http://code.google.com/p/sunrise/wiki/SfrhistConfigAndOutputFileFormat>
- Sufficient grid resolution is very important for converged results!
- Read the "ConvergenceTests" page on the Wiki!

Grid creation step 1

- First, subdivide cells until:
 - cells are no larger than the particles
 - optical depth through cells are below specified value:
 $\tau_{\text{tolerance}}$, or
 - max_level is reached
- This ensures all structure has been captured

Grid creation step 2

- Second, re-unify cells if:
 - they are sufficiently uniform (**metal_tolerance**), or
 - they are sufficiently low density they won't affect the result (**n_rays_estimated**), and
 - optical depth through unified cell still would be below **tau_tolerance**
- This minimizes the number of cells necessary

Initial conditions parameters

- Only applies if your simulation starts with pre-existing galaxies (and not for Gasoline)
- Need to specify SF history and metallicity distribution for these galaxies
 - `ic_file<i>` – a snapshot of the isolated progenitor galaxy
 - `(disk|bulge)popmode<i>` – the SF history (constant, exponential, or instantaneous)
 - `central_metallicity<i>`
 - `metallicity_gradient<i>`
- see special requirements for the snapshots

mcrx configuration

- Described in detail on the Wiki at "mcrx config and output file format"
- Many settings, quite complicated
 - camera setup parameters
 - dust model/dust emission parameters
 - monte carlo/radiation transfer parameters
 - runtime stuff

mcrx stages

- The calculation proceeds in several stages
 - Make images of stellar emission w/o dust
 - Make images of stellar emission w dust
 - Estimate stellar radiation intensity in cells
 - Calculate dust temperature and dust self-heating (iterative)
 - Make images of dust emission
- Can be restarted at any stage

Camera settings

- Cameras register the radiation reaching them from the simulated object
- Can be arranged isotropically or in individually specified positions
- Also defines their distance and resolution

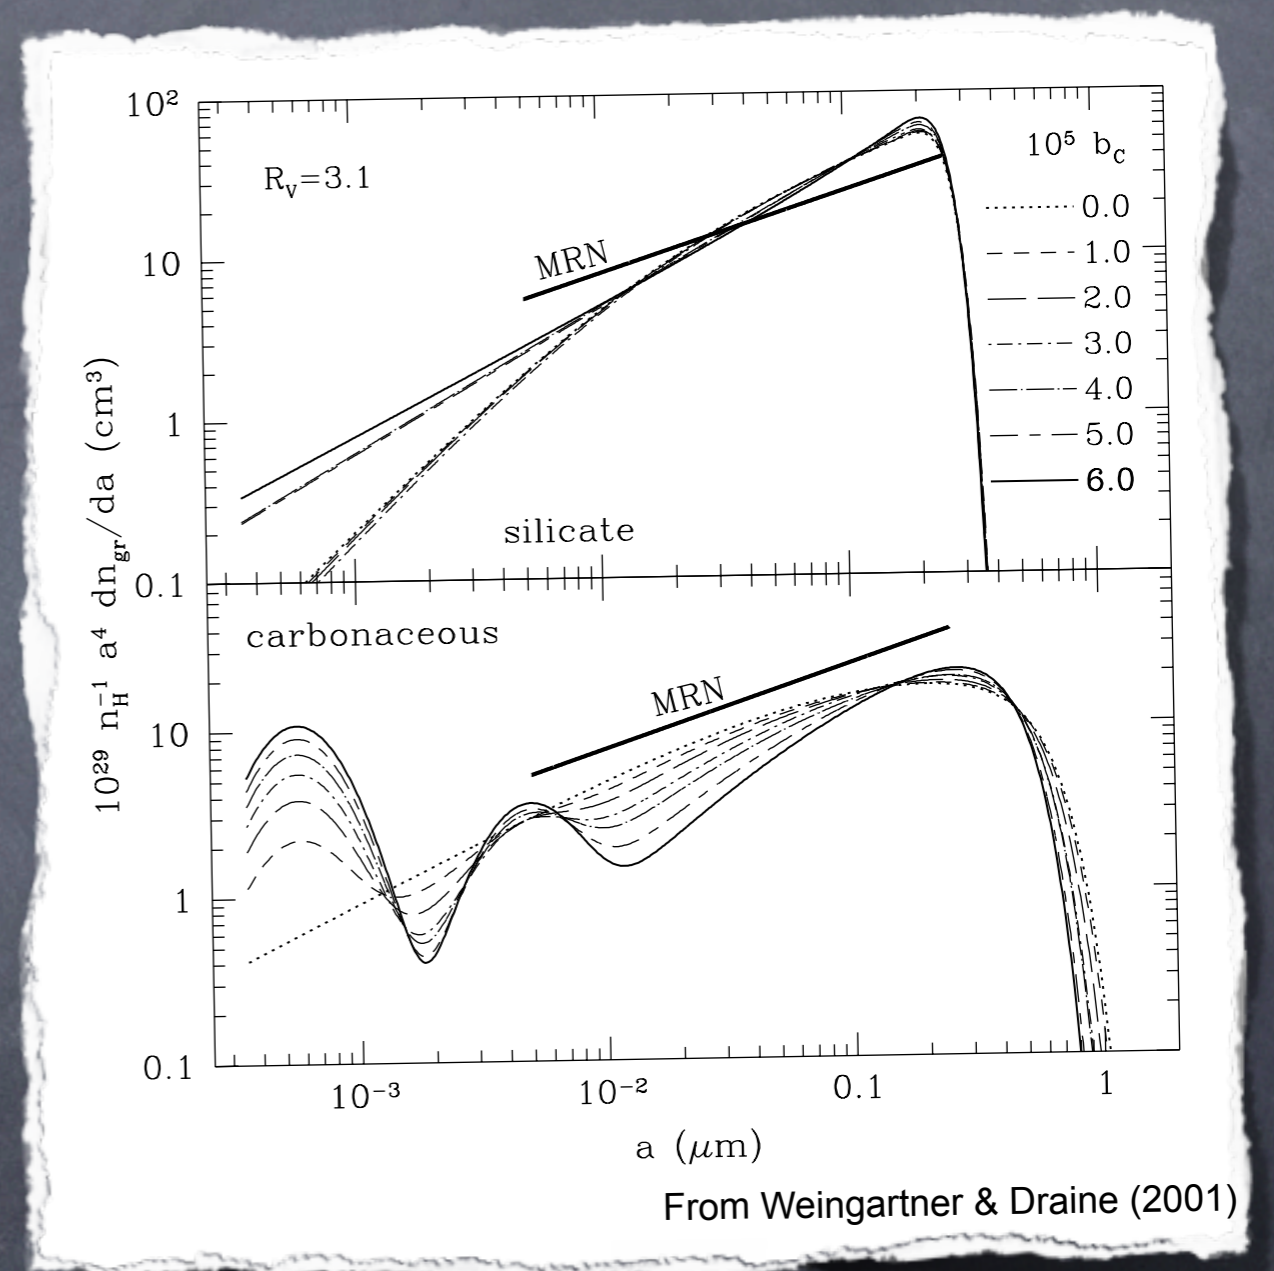

Dust model parameters

- A dust model specifies the dust opacities
- Two options:
 - If you don't care about dust emission, just specify opacity, albedo, scattering asymmetry
 - Otherwise, you need a full model of grain composition and size distribution.

Dust model parameters

- For a physical model, use `grain_model` `"wd01_Brent_PAH"`
- Picks a model from Weingartner & Draine (2001)
 - specify with `wd01_parameter_set`
 - e.g. `"MW3.1_60_DL07"`
 - Milky Way, LMC and SMC models exist

Dust density parameters

- Affects the conversion from density of gas and metals in the Gadget snapshot to density of dust
- `dust_to_metal_ratio` – normally 0.4
- `dust_to_gas_ratio` – normally 0
- Multiphase parameters

Multiphase model

- There's also clumps **without** embedded stars
- These still matter for the dust attenuation
- Can use Springel & Hernquist (03) multi-phase model to estimate mass in diffuse vs. clumps.
- Clumps are assumed to be dense enough to have negligible cross section

This option makes a **HUGE** difference in gas-rich mergers!

MC/Radiation transfer parameters

- Determines how the actual calculation is performed
 - The number of MC rays used (more rays, less noise, more time)
 - The ray intensity below which it may be dropped or above which it will be split
 - Reference wavelengths for the polychromatic algorithm
 - Number of wavelengths for the dust temperature determination
 - Accuracy with which radiative equilibrium is reached – **important**

MC/Radiation transfer parameters

- Determines how the actual calculation is performed
- The number of MC rays used (more rays, less noise, more time).
 - Typical values 10^6 – 10^7 .
 - Set separately for dust free, dusty
 - The ray intensity below which it may be dropped or above which it will be split
 - Reference wavelengths for the polychromatic algorithm
 - Number of wavelengths for the dust

Other stuff

- input file (!)
- output file
- the number of threads to use
- random seed
- whether to use a GPU
- self-documenting keywords (just get copied into the output file for your own reference)

broadband parameters

- Simple stuff
- Name of file specifying which filters you want
- Where to find the filter files
- Redshift
- Include Lyman alpha forest absorption?

A note about images

- The image outputs have units of surface brightness
 - $\text{W/m/m}^2/\text{sr}$
- Because surface brightness is independent of distance, it's only affected by redshift dimming and k-correction
- If you want the **flux**, you need to know the solid angle subtended by the pixels, and for that you need the angular diameter distance
- Sunrise does not do cosmology – this you need to do yourself

Working with Sunrise

Episode 4: Performance

Patrik Jonsson – HIPACC Summer School 2010

Performance

- Unlike (most of) the hydro codes you've heard about, Sunrise doesn't use MPI but pthreads
- One process per job means 1 node \Leftrightarrow 1 job
- Job sizes mostly limited by available memory
 - Want a lot of memory on the node (32GB enough for moderately large runs)
 - Many cores on the node
- Less memory required with fewer wavelengths and by skipping IR emission

Performance

- Runtime is 10 – 100 CPU hours per snapshot
- Depends on spatial & spectral resolution and optical thickness of model
- Can accelerate dust emission calculation with a GPU (see Lecture 4)
